CONSISTENCY OF KERNEL ESTIMATORS OF HETEROSCEDASTIC AND AUTOCORRELATED COVARIANCE MATRICES

BY ROBERT M. DE JONG AND JAMES DAVIDSON

1. INTRODUCTION

This paper derives conditions for the consistency of kernel estimators of the covariance matrix of a weighted sum of vectors of dependent heterogeneous random variables. This is a problem that has been studied recently by, among others, Newey and West (1987), Gallant and White (1988), Andrews (1991), Potscher and Prucha (1991b), Andrews and Monahan (1992), and Hansen (1992). A leading example of its application is where an estimator $\hat{\theta}_n (r \times 1)$ of a parameter $\theta_0$ is known to satisfy

$$n^{1/2}(\hat{\theta}_n - \theta_0) - B_n^{-1} \sum_{t=1}^n X_{nt}(\theta_0) \to 0$$

where the random function $X_{nt}(\theta) (p \times 1)$ has mean zero at $\theta_0$, and $B_n (r \times p)$ is some nonrandom matrix that is usually easily estimated.\(^2\) Applying a central limit theorem (CLT) to the second term in (1.1) leads to

$$\left( B_n \Omega_n B_n^t \right)^{-1/2} n^{1/2}(\hat{\theta}_n - \theta_0) \to d N(0, I_r)$$

where, letting $X_{nt} = X_{nt}(\theta_0)$,

$$\Omega_n = \sum_{t=1}^n \sum_{s=1}^n E X_{nt} X_{ns}^t.$$

A complete asymptotic distribution theory for $\hat{\theta}_n$ must incorporate whatever conditions are needed to ensure consistent estimation of $\Omega_n$ when the array $X_{nt}$ is dependently and heterogeneously distributed. An undesirable feature of the above-cited studies is that they impose conditions stronger in important respects than are known to be required for the application of a CLT to the same variables. All impose either a form of stationarity or uniform boundedness in $L_p$-norms for some $p \geq 2$, precluding trending moments. All except Potscher and Prucha (1991b) assume strong or uniform mixing, and also that the true covariance matrix converges to some well-defined limit. Finally, all except Hansen (1992) assume finite fourth moments. However, while the latter paper was the first to relax the moment restrictions, the proof contains an error (see de Jong (1999)), and the correction involves strengthening the necessary conditions on the bandwidth parameter, thereby limiting the scope of Hansen’s results.

In this paper, we will bridge the gap between asymptotic normality and consistent covariance matrix estimation by obtaining conditions for the latter similar to those obtained for the CLTs in Davidson (1992, 1993) and de Jong (1997). These are the best

\(^1\) We thank Benedict Potscher, a co-editor and three anonymous referees for their comments on the paper. The first author thanks Herman Bierens for discussion that eventually led to the proof of Lemma A.2. Responsibility for any errors is ours alone.

\(^2\) For example, in the linear regression model $y_t = \beta u + u$, we would have $X_{nt}(\theta_0) = n^{-1/2} z_t u_t$ and $B_n = n^{-1} \sum_{t=1}^n E z_t z_t^t$. 

407
such results for heterogeneous processes currently known to us. The weak dependence is characterized by near-epoch dependence on a mixing process, a more general property than mixing. We prove our results for stochastic (sample-dependent) bandwidths for the kernel estimators, and also show that in the standard cases, a sufficient condition on the bandwidth for consistency of the variance estimator is that its ratio with the sample size converges to zero. Of the above-cited references only Andrews (1991) gives results that allow for such a behavior of the bandwidth, although under stronger assumptions. Our central result shows convergence to zero of the difference between the elements of the estimated and the true covariance matrix. There is no need to assume that the true covariance matrix itself converges to a well-defined limit. We will argue that relaxing the so-called size conditions on the sequences measuring dependence for the case of covariance matrix estimation for root-$n$ consistent minimization estimators is not possible, and in that sense, our dependence conditions are the best possible. Finally, we are able to generalize from the root-$n$ consistency represented in (1.2), by giving results subject to the condition

$$n^{1/2} \kappa_n(\hat{\theta} - \theta_0) = O_p(1)$$

where $\kappa_n$ is a diagonal matrix function of $n$. This permits such applications as the Phillips-Perron (1988) unit root test and the Phillips-Hansen (1990) fully modified least squares estimator, but our assumptions also permit nonlinear models involving deterministic or stochastic trends.

Section 2 of the paper will present our main results. The proofs can be found in the Appendix.

### 2. MAIN RESULTS

The consistency results are inspired by the proofs of the CLTs for possibly trending-variance processes in Davidson (1992, 1993), and de Jong (1997), in which showing the consistency of a certain variance estimate is an essential step. Let

$$\hat{\Omega}_n = \sum_{t=1}^{n} \sum_{s=1}^{n} X_{nt} X_{ns} k((t-s)/\gamma_n),$$

where $k(\cdot)$ is called the kernel function, and $\gamma_n$, the bandwidth or lag truncation parameter, is an increasing function of $n$. $X_{nt}$ ($p \times 1$) is to be thought of as a random function of parameters $\theta$ ($r \times 1$), which unless we indicate otherwise is evaluated at the true parameter point $\theta_0 \in \Theta$, where $\Theta$ is a compact, convex subset of $\mathbb{R}^r$. More generally we write $X_{nt}(\theta)$, and our operational estimator is

$$\hat{\Omega}_n(\hat{\theta}_n) = \sum_{t=1}^{n} \sum_{s=1}^{n} X_{nt}(\hat{\theta}_n) X_{ns}(\hat{\theta}_n)' k((t-s)/\gamma_n).$$

The array notation allows us to generalize our results, but direct comparability with those of Andrews (1991) and Hansen (1992) is obtained by considering the case $X_{nt} = n^{-1/2} X_t$. In this case, (2.1) becomes

$$\hat{\Omega}_n = n^{-1} \sum_{t=1}^{n} \sum_{s=1}^{n} X_t X_s' k((t-s)/\gamma_n).$$

We assume that $k(\cdot)$ belongs to the function class $K$, defined as follows.
ASSUMPTION 1: \( k(\cdot) \in \mathbb{K}, \) where

\[
K = \left\{ k(\cdot): \mathbb{R} \rightarrow [-1, 1] | k(0) = 1, k(x) = k(-x) \ \forall x \in \mathbb{R}, \right. \\
\int_{-\infty}^{\infty} |k(x)| \, dx < \infty, \int_{-\infty}^{\infty} \left| \psi(\xi) \right| \, d\xi < \infty,
\]

\( k(\cdot) \) is continuous at 0 and at all but a finite number of points\),

where

\[
\psi(\xi) = (2\pi)^{-1} \int_{-\infty}^{\infty} k(x)e^{i\xi x} \, dx.
\]

In Andrews (1991), function classes \( \mathbb{K}_1 \) and \( \mathbb{K}_2 \) are defined. Our class \( \mathbb{K} \) contains Andrews' class \( \mathbb{K}_2 \), since his requirement \( \psi(\xi) \geq 0 \) is replaced by \( \int_{-\infty}^{\infty} \psi(\xi) \, d\xi < \infty \), a weaker condition in view of the fact that \( \int_{-\infty}^{\infty} \psi(\xi) \, d\xi = k(0) = 1 \). As Andrews notes, the class \( \mathbb{K}_2 \) corresponds to that for which \( \Omega(z) \) is positive semidefinite with probability one, and hence class \( \mathbb{K} \) contains these cases. The Bartlett, Parzen, Quadratic Spectral, and Tukey-Hanning kernels, although not the truncated kernel, are all included in \( \mathbb{K} \).

We need the following assumptions linking the dependence and heterogeneity of the processes and the permitted bandwidth. First, recall that \( X_{nt} \) is said to be \( L_2 \)-near epoch dependent of size \( r \) on a strong mixing resp. uniform mixing random array \( V_{nt} \) of size \( r \) and there exists a triangular constant array \( c_{nt} \) such that

\[
\sup_{n \geq 1} \sup_{1 \leq t \leq n} (\|X_{nt}\|_r + d_{nt}) / c_{nt} < \infty,
\]

for some \( r > 2 \), and

\[
\sup_{n \geq 1} \sum_{t=1}^{n} c_{nt}^2 < \infty.
\]

Under uniform mixing, \( r = 2 \) is also permitted if \( |X_{nt}|^2 / c_{nt}^2 \) is uniformly integrable.

ASSUMPTION 3: \( \lim_{n \to \infty} (\gamma_0 - 1 + \gamma_0 \max_{1 \leq t \leq n} c_{nt}^2) = 0. \)

Note that the definition of class \( \mathbb{K}_2 \) in Andrews (1991) specifies square-integrability of \( k \), which is incorrect. This is corrected to absolute integrability (as here) in Andrews and Monahan (1992); see the footnote on page 955.

4 The Tukey-Hanning and truncated kernels belong to Andrews' (1991) \( \mathbb{K}_2 \) class, but not to \( \mathbb{K}_2 \).

The Bartlett, Parzen, Quadratic Spectral, and Tukey-Hanning kernels, although not the truncated kernel, are all included in \( \mathbb{K} \).

In this paper, the \( L_q \)-norm of a random matrix \( X \) is defined as \( \|X\|_q = (\Sigma_{i} \Sigma_{j} E |X_{ij}|^q)^{1/q} \) for \( q \geq 1 \). Similarly, \( |.| \) denotes the Euclidean norm of the appropriate dimension.
The reference case of the constant array specified here is simply $c_{nt} = n^{-1/2}$, corresponding to $X_{nt} = n^{-1/2}X_t$ where $X_t$ is a stationary sequence. See Davidson (1992, 1993), de Jong (1997) for a discussion of other examples involving trends. These dependence conditions match those of the best central limit theorems for NED /mixing arrays. It also can be shown (see de Jong (1997) and Doukhan, Massart, and Rio (1994)) that relaxing the strong mixing size requirement on $V_{nt}$, or the $L^2$-NED size requirement on $X_{nt}$, implies that the latter need not be covariance summable. In the reference case of (1.1) with $B_n = B$, this would imply that $n^{-1}E(\sum_{t=1}^n X_t)\sum_{t=1}^n X_t' \to \infty$ as $n \to \infty$, so that (1.1) would be incompatible with root-$n$ consistency of $\hat{\theta}_n$. For this case our result is in effect the best possible with respect to dependence conditions, when dependence is characterized by Assumption 2.

In the reference case, Assumption 3 permits $\gamma_n = o(n)$. For comparison, order of magnitude limits placed on the bandwidth in previous consistency proofs under differing regularity conditions, although generally stronger than ours include $o(n^{1/4})$ by Newey and West (1987), $o(n^{1/3})$ by Pötscher and Prucha (1991b), $o(n^{1/2})$ by Kool (1988) and Hansen (1992), and $o(n)$ by Andrews (1991). These assumptions suffice for consistency of $\hat{\Omega}_n$ in (2.1), in which $\theta_0$ is implicitly known.

**Theorem 2.1:** Under Assumptions 1, 2, and 3,

$$\hat{\Omega}_n - \Omega_n \overset{p}{\to} 0.$$ 

The next step is to show that $\hat{\Omega}_n(\hat{\theta}_n)$ is asymptotically equivalent to $\hat{\Omega}_n$. For this we need the following extra assumption.

**Assumption 4:** (a) $n^{1/2}K_n(\hat{\theta}_n - \theta_0) = O(1)$, where $K_n = \text{diag}(\kappa_1, \ldots, \kappa_n)$ is a deterministic $r \times r$ matrix; (b) $n^{-1/2}K_n^{-1}\sum_{t=1}^n E \partial X_n(\theta)/\partial \theta'$ is continuous at $\theta_0$ uniformly in $n$; (c) there exists $N_0 < N$, an open neighborhood of $\theta_0$, such that,

$$\limsup_{n \to \infty} \frac{1}{n} \sum_{t=1}^n E \sup_{\theta \in N} \left| K_n^{-1} \frac{\partial X_n(\theta)}{\partial \theta'} \right|^2 < \infty,$$

and either (i)

$$\sup_{\theta \in N} \left| n^{-1/2}K_n^{-1} \sum_{t=1}^n \xi \frac{\partial X_n(\theta)}{\partial \theta} \right| \to 0$$

for all $\xi \in \mathbb{R}$, or (ii), $n^{-1/2} \gamma_n = o(1)$ and

$$\sup_{\theta \in N} \left| \sum_{t=1}^n \kappa_n^{-1} \frac{\partial X_n(\theta)}{\partial \theta} \frac{\partial X_n(\theta)}{\partial \theta'} \kappa_n^{-1} \right| = O_P(1).$$

Andrews (1991) also shows that bandwidths growing faster than $o(n^{1/2})$ can never be optimal under a mean squared error optimality criterion. However, the MSE condition is only relevant when fourth moments of the data exist, and hence for only a subset of the cases covered by our assumptions.
In case (1.1) for example, we would set \( \kappa_n = 1 \). For a different choice of \( \kappa_n \), Assumption 4(a) allows the elements of \( \hat{\theta} \) to converge at different rates.

**Theorem 2.2:** Under Assumptions 1, 2, 3, and 4,

\[
\hat{\Omega}_n(\hat{\theta}_n) - \Omega_n \xrightarrow{p} 0.
\]

If Assumption 4(i) applies, Assumption 3 represents the only restrictions on the bandwidth for this result. The complex-valued weights in (2.9) lie on the unit circle, and, if it holds in their absence, a uniform law of large numbers for heterogeneous processes could usually be adapted to this case by considering the real and imaginary parts separately. Lower-level assumptions sufficient for the convergence in \( L^2 \) cannot be cited without referring specifically to the functional form of \( X_n(\theta) \), but we note that arbitrary mixing and NED sizes are often sufficient, and various results exist for extending the NED property to transformations of an NED process. It might suffice merely to extend Assumption 2 to hold uniformly on \( N \), for example. Also note, in this connection, that conditions similar to Assumption 4(i) often need to be invoked to prove the convergence represented in (1.1).

A supposition 4(ii) accommodates processes with deterministic or stochastic trends, and in a linear model, corresponds to Assumption V3 of Hansen (1992). Thus, letting \( W_t \) \((r \times 1)\) represent an i.i.d vector of cointegrated variables, suppose \( X_n(\hat{\theta}_n) = n^{-1/2} \hat{\theta}_n W_n \) is the normalized OLS residual. \( \hat{\theta}_n \) is \( n \)-consistent and we can set \( \kappa_n = n^{1/2} \). In this case the assumption is trivially satisfied under standard regularity conditions, although note that assumption 4(i) fails because with \( I(1) \) variables, the array in (2.9) converges weakly to a random limit, but not in probability. However, unlike Hansen’s, our assumption still allows the gradient to depend on \( \theta \) and accordingly permits nonlinear models involving trends.

We lastly establish a result that allows bandwidths to be stochastic. See Andrews and Monahan (1992) and Newey and West (1994) for discussion of such procedures. While the optimal bandwidths discussed in those papers are justified on the MSE criterion, which is available only when fourth moments exist, our result can be thought of as reassuring practitioners of the consistency of these estimators even if the fourth moment condition fails. Let \( \hat{\Omega}_n(\hat{\theta}_n, \hat{\gamma}_n) \) denote \( \hat{\Omega}_n(\hat{\theta}_n) \) as before, but evaluated at the possibly stochastic bandwidth \( \hat{\gamma}_n \) instead of \( \gamma_n \).

**Theorem 2.3:** Assume that Assumptions 1, 2, 3, and 4 hold. In addition, assume that \( \hat{\theta}_n = \hat{\alpha}_n \gamma_n \), where \( \hat{\alpha}_n = O_p(1) \) and \( 1/\hat{\alpha}_n = O_p(1) \). \( \gamma_n \) satisfies the bandwidth conditions of the assumptions, and for all \( \epsilon \in (0, 1) \), \( k(\cdot) \) satisfies

\[
(2.11) \quad \int_{-\infty}^\infty \sup_{\alpha \in [\epsilon, 1/\epsilon]} |k(\alpha x)| \, dx < \infty
\]

and

\[
(2.12) \quad \int_{-\infty}^\infty \sup_{\alpha \in [\epsilon, 1/\epsilon]} |\psi(\alpha \xi)| \, d\xi < \infty.
\]

\(^7\text{See Davidson (1994, Chapters 17 and 19) for further information on these issues.}\)
Then
\[
(2.13) \quad \hat{\Omega}_n(\hat{\delta}_n, \hat{\delta}_n) - \Omega_n^\beta = 0.
\]

Note that the conditions on \(k(\cdot)\) that are imposed in Theorem 2.3 are satisfied for the Bartlett, Parzen, Quadratic Spectral, and Tukey-Hanning kernels.

\section*{Appendix: Proofs}

In the proofs and associated lemmas we assume for simplicity that \(X_{nt}\) is real-valued (i.e. \(p = 1\)). As pointed out by Newey and West (1987), the results can be extended directly to vector-valued \(X_{nt}\), provided the assumptions hold for the scalars \(\lambda'X_{nt}\) for all conformable nonzero fixed vectors \(\lambda\).

The proofs require the mixingale concept. Let \(H_n\) denote an array of \(\sigma\)-fields that is nondecreasing in \(t\) for each \(n\). The array \((Y_{nt}, H_n)\), is called an \(L_2\)-mixingale of size \(-\lambda\) if for a triangular constant array \(c_n\) (the mixingale magnitude indices)

\begin{align}
(A-1) \quad \|Y_{nt} - E(Y_{nt}|H_{n,t+m})\|_2 & \leq c_n \psi(m + 1), \\
(A-2) \quad E(Y_{nt}|H_{n,t-m}) & \leq c_n \psi(m),
\end{align}

for \(m \geq 0\), and \(\psi(m) = O(m^{-\lambda - \epsilon})\) for some \(\epsilon > 0\). Assumption 2 implies that \((Y_{nt}, H_n)\) is a mixingale of size \(-1/2\) with mixingale magnitude indices \(c_n\) as defined therein, for \(H_n = \sigma(V_{nt}, V_{n,t-1}, \ldots)\). This follows by Theorem 17.5 of Davidson (1994). In this Appendix, \(H_n\) will denote this sigma field. We will make use of the following result (Theorem 1.6 of McLeish (1975)):

\begin{lemma}
Let \((Y_{nt}, H_n)\) be a real valued \(L_2\)-mixingale of size \(-1/2\) with mixingale magnitude indices \(c_n\). Then \(E(\sum_{t=1}^n Y_{nt}^2) = O(\sum_{t=1}^n c_n^2)\).
\end{lemma}

\begin{proof}[Proof of Theorem 2.1]
Define \(b_n = [\gamma_n/\delta]\) and \(r_n = [n/b_n]\) where \([x]\) denotes the largest integer not exceeding \(x\),

\begin{align}
(A-3) \quad \gamma_n(x) & = (\delta^2 2\pi)^{-1/2} \exp(-x/2), \\
(A-4) \quad \Omega_{1n}^\alpha & = \sum_{t=-n+1}^{2n} \gamma_n^{-1/2} \langle \sum_{l=1}^{n-t} X_{n,t+l} k(l/\gamma_n) 1_{[0,\gamma_n]}(||) \rangle \\
& \times \langle \sum_{j=1-t}^{n-t} X_{n,t+j} \gamma_n(j/\gamma_n) \rangle, \\
(A-5) \quad \Omega_{2n}^\alpha & = \sum_{t=-n+1}^{2n} \gamma_n^{-1/2} \langle \sum_{l=1}^{n-t} X_{n,t+l} k(l/\gamma_n) 1_{[0,\gamma_n]}(||) \rangle \\
& \times \langle \sum_{j=1-t}^{n-t} X_{n,t+j} \gamma_n(j/\gamma_n) \rangle,
\end{align}

\end{proof}
and

\[ \Omega_{2n\delta} = \sum_{t = -n+1}^{2n} \left( \gamma_n^{-1/2} \sum_{j = 1}^{n-t} X_{n,t+j} k(1/\gamma_n) 1_{(0,b_n)}(||j||) \right) \times \left( \gamma_n^{-1/2} \sum_{j = 1}^{n-t} X_{n,t+j} k(1/\gamma_n) 1_{(0,b_n)}(||j||) \right), \]

where \( 1_{[a,b)} \) denotes the indicator function of the interval \([a,b)\). Note that

\[ ||\hat{\Omega}_n - \Omega_n||_1 \leq ||\hat{\Omega}_n - \Omega_{2n\delta}||_1 + ||\Omega_{2n\delta} - \Omega_{2n\delta}||_1 + ||\Omega_{2n\delta} - \Omega_{2n\delta}||_1 \]

The four lemmas that follow show that each of the terms on the right-hand side of (A-7) vanishes if we first take the lim sup as \( n \) approaches infinity and then, if required, the limit as \( \delta \to 0 \). Q.E.D.

**Lemma A.2:** Under Assumption 1, 2, and 3,

\[ \lim_{\delta \to 0} \limsup_{n \to \infty} ||\hat{\Omega}_n - \Omega_{2n\delta}||_1 = 0. \]

**Proof:** First note that \( k(x) = \int_{-\infty}^{\infty} \exp(i\xi x) \psi(\xi) \, d\xi \), by the inversion formula for Fourier transforms. Therefore, using the fact that \( k(\cdot) \) and hence \( \phi(\cdot) \) are even functions,

\[ \hat{\Omega}_n = \int_{-\infty}^{\infty} \left( \sum_{t = 1}^{\infty} X_{nt} \cos(t\xi/\gamma_n) \right)^2 \times \left( \sum_{t = 1}^{\infty} X_{nt} \sin(t\xi/\gamma_n) \right)^2 \psi(\xi) \, d\xi. \]

Next, note that

\[ \Omega_{2n\delta} = \sum_{t = 1}^{n} \sum_{s = 1}^{n} X_{nt} X_{ns} k_{n\delta}(t-s)/\gamma_n, \]

where

\[ k_{n\delta}(x) = \gamma_n^{-1} \sum_{l = -n}^{n} k(1/\gamma_n) \eta_0(x+1/\gamma_n). \]

The inverse Fourier transform of \( k_{n\delta}(\cdot) \) can be shown to be

\[ (2\pi)^{-1} \int_{-\infty}^{\infty} e^{-i\xi} k_{n\delta}(x) \, dx = \phi_n(\xi) e^{-\xi^2/2} \]

where

\[ \phi_n(\xi) = (\gamma_n 2\pi)^{-1} \sum_{l = -n}^{n} k(1/\gamma_n) e^{i\xi/\gamma_n}. \]
and note that for all \( x \in \mathbb{R}, \lim_{n \to \infty} \psi_n(x) = \psi(x) \). From the representation of equation (A-8) and the properties of \( \| \cdot \|_1 \), it follows that
\[
(A-13) \quad \| \hat{\Omega}_n - \Omega_{1n} \|_1 \leq \int_{-\infty}^{\infty} \left( E \left( \sum_{t=1}^{n} X_n \cos(t \xi / \gamma_n) \right)^2 + E \left( \sum_{t=1}^{n} X_n \sin(t \xi / \gamma_n) \right)^2 \right) \times |\psi(\xi) - \psi_n(\xi) e^{-\delta^2 \xi^2 / 2}| d\xi.
\]
Therefore, by Lemma A.1,
\[
(A-14) \quad \| \hat{\Omega}_n - \Omega_{1n} \|_1 = O \left( \int_{-\infty}^{\infty} |\psi(\xi) - \psi_n(\xi) e^{-\delta^2 \xi^2 / 2}| d\xi + \int_{-\infty}^{\infty} |\psi(\xi) - \psi_n(\xi) | e^{-\delta^2 \xi^2 / 2} d\xi \right)
\]
and by first taking the \( \lim_{n \to \infty} \) as \( n \) and then the limit as \( \delta \to 0 \), the result follows by dominated convergence. Q.E.D.

**Lemma A.3:** Under Assumptions 1, 2, and 3,
\[
(A-15) \quad \lim_{\delta \to 0} \lim_{n \to \infty} \| \Omega_{1n} - \Omega_{2n} \|_1 = 0,
\]
and
\[
(A-16) \quad \lim_{\delta \to 0} \lim_{n \to \infty} \| \Omega_{2n} - \Omega_{3n} \|_1 = 0.
\]

**Proof:** We prove (A-15), the case of (A-16) being similar.
\[
(A-17) \quad \| \Omega_{1n} - \Omega_{2n} \|_1 = \left\| \sum_{t=-n+1}^{2n} \gamma_n^{-1/2} \sum_{l=1-t}^{n-t} X_{n,t+1} k(1/\gamma_n) 1_{[0,n]}' 1_{[b_{n+1},s]} \right\|_1
\]
\[
\times \left\| \gamma_n^{-1/2} \sum_{j=1}^{n-t} X_{n,t+1} \eta_n(j/\gamma_n) \right\|_1
\]
\[
\leq \left( \sum_{t=-n+1}^{2n} \gamma_n^{-1} \sum_{l=1-t}^{n-t} c_{n,t+1}^2 k(1/\gamma_n)^2 1_{[b_{n+1},s]} \right)^{1/2}
\]
\[
\times \left( \sum_{t=-n+1}^{2n} \gamma_n^{-1} \sum_{j=1}^{n-t} c_{n,t+1}^2 \eta_n(j/\gamma_n)^2 \right)^{1/2}
\]
\[
- O \left( \int_{1/\delta}^{\infty} k(x)^2 dx \right)^{1/2} \to 0
\]
as \( \delta \to 0 \), where the inequality is got by successively applying the Cauchy-Schwarz inequality, Lemma A.1, and a second application of Cauchy-Schwarz. Q.E.D.
LEMMA A.4: Under Assumptions 1, 2, and 3,

(A-18) \( \lim_{n \to \infty} \| \Omega_{3n, \delta} - E \Omega_{3n, \delta} \|_1 = 0 \)

for all \( \delta > 0 \).

PROOF: Write

(A-19) \( \Omega_{3n, \delta} = \sum_{t=1}^{2n} Y_{nt} Z_{nt} \)

where

(A-20) \( Y_{nt} = \gamma_n^{-1/2} \sum_{i=1}^{n-t} X_{n, t+i} k((1/\gamma_n) 1_{[0, b_n]}(i)) \).

(A-21) \( Z_{nt} = \gamma_n^{-1/2} \sum_{j=1}^{n-t} X_{n, t+j} \eta_j (1/\gamma_n) 1_{[0, b_n]}(j) \).

Note that these are sums of at most \( b_n \) terms. Also define

(A-22) \( \phi_n^2 = \gamma_n^{-1} \sum_{i=1}^{n-t} c_{n, t+i}^2 k((1/\gamma_n)^2 1_{[0, b_n]}(i)) \).

(A-23) \( \psi_n^2 = \gamma_n^{-1} \sum_{j=1}^{n-t} c_{n, t+j}^2 \eta_j (1/\gamma_n)^2 1_{[0, b_n]}(j) \).

Note that \( Y_{nt}/\phi_n^2 \) and \( Z_{nt}/\psi_n^2 \) are uniformly integrable by Lemma 3.2 of Davidson (1992) and the discussion following that lemma. Define \( h(K, x) = x^2 - Kx, K(x) = K 1_{x=0}(x) - K 1_{x<0}(x) \), and let \( K \) be some constant to be chosen. Let \( Y_{nt} = h(K, \phi_{nt}, Y_{nt}) \) and \( Z_{nt} = h(K, \psi_{nt}, Z_{nt}) \). Then we have

(A-24) \( \limsup_{n \to \infty} \left\| \sum_{t=-n}^{2n} Y_{nt} Z_{nt} - \bar{Y}_{nt} \bar{Z}_{nt} \right\|_1 \)

\( \leq \limsup_{n \to \infty} \left( \left\| \sum_{t=-n}^{2n} Y_{nt} Z_{nt} 1_{(K, \phi_{nt})} = (Y_{nt}) \right\|_1 \right) \)

\( + \left\| \sum_{t=-n}^{2n} Y_{nt} Z_{nt} 1_{(K, \phi_{nt})} = (Z_{nt}) \right\|_1 \)

\( \leq C \left( \sup_{t, n \geq 1} E \left( \frac{Y_{nt}^2}{\phi_{nt}^2} \right) 1_{(K, \phi_{nt})} \left( \frac{Y_{nt}^2}{\phi_{nt}^2} \right)^{1/2} \right) \)

\( + C \left( \sup_{t, n \geq 1} E \left( \frac{Z_{nt}^2}{\psi_{nt}^2} \right) 1_{(K, \psi_{nt})} \left( \frac{Z_{nt}^2}{\psi_{nt}^2} \right)^{1/2} \right) \)

\( < \eta \)

for some constant \( C > 0 \) by a large enough choice of \( K_{\eta} \) and because

(A-25) \( \sup_{n \geq 1} \sum_{t=-n}^{2n} (\phi_{nt}^2 + \psi_{nt}^2) < \infty \)
by assumption. Next, note that for \( \hat{Y}_{nt}, \tilde{Z}_{nt} \), we have for \( m \geq 0 \)

\[
(A-26) \quad \left\| \hat{Y}_{nt} \tilde{Z}_{nt} - E \left( \hat{Y}_{nt} \tilde{Z}_{nt} \mid V_{nt-b_m} \right) \right\|_2 \\
\leq \left\| \left( \tilde{Z}_{nt} - E \left( \tilde{Z}_{nt} \mid V_{nt-b_m} \right) \right) \hat{Y}_{nt} \right\|_2 + \left\| E \left( \hat{Y}_{nt} \mid V_{nt-b_m} \right) \left( \hat{Y}_{nt} - E \left( \hat{Y}_{nt} \mid V_{nt-b_m} \right) \right) \right\|_2 \\
\leq \| \tilde{Z}_{nt} \|_2 \left\| \hat{Y}_{nt} - E \left( \hat{Y}_{nt} \mid V_{nt-b_m} \right) \right\|_2 + \left\| E \left( \hat{Y}_{nt} \mid V_{nt-b_m} \right) \left( \hat{Y}_{nt} - E \left( \hat{Y}_{nt} \mid V_{nt-b_m} \right) \right) \right\|_2 \\
= O \left( m^{-1/2} r_n^{-1} \sum_{j=1-t}^{n-t} c_n^{2} \mu_{j+1} [0, b_n (|j|)] \right),
\]

for \( \varepsilon > 0 \), in view of the near-epoch dependence assumption on \( X_{nt} \).

We now introduce a blocking scheme. Define \( r'_n = \lfloor 3n / 2b_n \rfloor \), and note that

\[
(A-27) \quad \sum_{t = -n+1}^{2n} \hat{Y}_{nt} \tilde{Z}_{nt} = \sum_{i=1}^{r'_n} \sum_{t=(2i-1)b_n-n+1}^{2i b_n-n} \hat{Y}_{nt} \tilde{Z}_{nt} \\
+ \sum_{i=1}^{r'_n} \sum_{t=(2i-1)b_n-n+1}^{2i b_n-n} \hat{Y}_{nt} \tilde{Z}_{nt} + \sum_{t=r'_n b_n-n+1}^{2n} \hat{Y}_{nt} \tilde{Z}_{nt} \\
= \sum_{i=1}^{r'_n} U_{ni} + \sum_{i=1}^{r'_n} U_{ni} + \sum_{t=r'_n b_n-n+1}^{2n} \hat{Y}_{nt} \tilde{Z}_{nt}.
\]

For the last term, we have

\[
(A-28) \quad \left\| \sum_{t=r'_n b_n-n+1}^{2n} \hat{Y}_{nt} \tilde{Z}_{nt} \right\|_2 = O \left( b_n \max_{1 \leq t \leq n} c_n^{2} \right) = o(1)
\]

by assumption. We will analyze the sum of the \( U_{ni} \), noting that the case of the \( U_{ni} \) is analogous. The assertion of the lemma follows if we can show that the first term of Equation (A-27) obeys a law of large numbers. Define

\[
W_{n, i}^{+m} = \sigma \left( \left( V_{n, (2i-1)b_n-n+1, \ldots, V_{n, (2i+m-1)b_n-n} \right) \right)
\]

and note that \( U_{ni} \) is near epoch dependent on \( W_{ni} \) because for \( m \geq 1 \)

\[
(A-29) \quad \left\| U_{ni} - E \left( U_{ni} \mid W_{ni, i-m}^{+m} \right) \right\|_2 \\
\leq \sum_{t=(2i-1)b_n-n+1}^{(2i-1)b_n-n} \left\| \hat{Y}_{nt} \tilde{Z}_{nt} - E \left( \hat{Y}_{nt} \tilde{Z}_{nt} \mid W_{ni, i-m}^{+m} \right) \right\|_2 \\
\leq \sum_{t=(2i-1)b_n-n+1}^{(2i-1)b_n-n} \left\| \hat{Y}_{nt} \tilde{Z}_{nt} - E \left( \hat{Y}_{nt} \tilde{Z}_{nt} \mid V_{nt-(i-m)b_n} \right) \right\|_2 \\
= O \left( m^{-1/2} r_n^{-1} \sum_{t=(2i-1)b_n-n+1}^{(2i-1)b_n-n} \sum_{t=1-t}^{n-t} c_n^{2} \mu_{j+1} [0, b_n (|j|)] \right)
\]
where the second inequality follows because $V_{n,t-m} \leq W_{n,t-m}^{2}$ for $t \in [(2i-1)b_n - n + 1, (2i-1)b_n - n]$, and the last step is by (A-26). For $m = 0$, the relevant result is

$$\|U_n - E(U_n|W_n^i)|_2 \leq 2\|U_n\|_2$$

We conclude that $U_n$ is also an $L^2$-mixingale of size $-1/2$ with respect to the $F_n = \sigma(V_n,2b_n-e, V_n,2b_n-e-1, \ldots)$ because for all $m \geq 1$

$$\|E(U_n|F_{n,i-2m}) - E(U_n)\|_2$$

similarly to Davidson (1994, Theorem 17.5). For $m = 0$, the result from Equation (A-30) can again be used. Finally, note that from Lemma A.1 it follows that

$$\sum_{i=1}^{r_n} h_{n1}^2$$

where the $h_{n1}$ denote the mixingale magnitude indices of $U_n$. Therefore, the lemma holds because

$$\lim_{n \to \infty} \sum_{i=1}^{r_n} \left( \gamma_n^{-1} \sum_{t=(2i-2)b_n - n + 1}^{(2i-2)b_n - n - 1} \sum_{j=1-t}^{n-t} c_{n,t+j}^2 b_n(j) \right)^2$$

$$\leq \lim_{n \to \infty} \sum_{i=1}^{r_n} \gamma_n^{-1} \sum_{t=(2i-2)b_n - n + 1}^{(2i-2)b_n - n - 1} \sum_{j=1-t}^{n-t} c_{n,t+j}^2 b_n(j)$$

$$\times \max_{1 \leq i \leq r_n} \gamma_n^{-1} \sum_{t=(2i-2)b_n - n + 1}^{(2i-2)b_n - n - 1} \sum_{j=1-t}^{n-t} c_{n,t+j}^2 b_n(j)$$

$$= O(\gamma_n \max_{1 \leq i \leq n} c_{n,t}^2) = o(1)$$

under the conditions stated.

**Lemma A.5:** Under Assumptions 1, 2, and 3,

$$\lim_{n \to \infty} |E(\hat{\Omega}_n - \Omega_n)| = 0.$$

**Proof:** Let $Y_{tk} = E(X_{nt}|H_{n,t-k}) - E(X_{nt}|H_{n,t-k-1})$, and note that

$$X_{nt} = \sum_{k=-n}^{n} Y_{tk}$$

and also that

$$\sum_{i=m}^{n} Y_{tk} Y_{t+i} = 0$$

unless $i = k$. Further, letting

$$E Y_{tk} = \|E(X_{nt}|H_{n,t-k})\|_2$$

where the second inequality follows because $V_{n,t-m} \leq W_{n,t-m}^{2}$ for $t \in [(2i-1)b_n - n + 1, (2i-1)b_n - n]$, and the last step is by (A-26). For $m = 0$, the relevant result is

$$\|U_n - E(U_n|W_n^i)|_2 \leq 2\|U_n\|_2$$

We conclude that $U_n$ is also an $L^2$-mixingale of size $-1/2$ with respect to the $F_n = \sigma(V_n,2b_n-e, V_n,2b_n-e-1, \ldots)$ because for all $m \geq 1$

$$\|E(U_n|F_{n,i-2m}) - E(U_n)\|_2$$

similarly to Davidson (1994, Theorem 17.5). For $m = 0$, the result from Equation (A-30) can again be used. Finally, note that from Lemma A.1 it follows that

$$\sum_{i=1}^{r_n} h_{n1}^2$$

where the $h_{n1}$ denote the mixingale magnitude indices of $U_n$. Therefore, the lemma holds because

$$\lim_{n \to \infty} \sum_{i=1}^{r_n} \left( \gamma_n^{-1} \sum_{t=(2i-2)b_n - n + 1}^{(2i-2)b_n - n - 1} \sum_{j=1-t}^{n-t} c_{n,t+j}^2 b_n(j) \right)^2$$

$$\leq \lim_{n \to \infty} \sum_{i=1}^{r_n} \gamma_n^{-1} \sum_{t=(2i-2)b_n - n + 1}^{(2i-2)b_n - n - 1} \sum_{j=1-t}^{n-t} c_{n,t+j}^2 b_n(j)$$

$$\times \max_{1 \leq i \leq r_n} \gamma_n^{-1} \sum_{t=(2i-2)b_n - n + 1}^{(2i-2)b_n - n - 1} \sum_{j=1-t}^{n-t} c_{n,t+j}^2 b_n(j)$$

$$= O(\gamma_n \max_{1 \leq i \leq n} c_{n,t}^2) = o(1)$$

under the conditions stated.

**Q. E. D.**

**Lemma A.5:** Under Assumptions 1, 2, and 3,

$$\lim_{n \to \infty} |E(\hat{\Omega}_n - \Omega_n)| = 0.$$

**Proof:** Let $Y_{tk} = E(X_{nt}|H_{n,t-k}) - E(X_{nt}|H_{n,t-k-1})$, and note that

$$X_{nt} = \sum_{k=-n}^{n} Y_{tk}$$

and also that

$$\sum_{i=m}^{n} Y_{tk} Y_{t+i} = 0$$

unless $i = k$. Further, letting

$$E Y_{tk} = \|E(X_{nt}|H_{n,t-k})\|_2$$
where on the assumptions, \( m \log T \) and \( c \) we have

\[
\|X_{t+1} - X_t\|^2 = \left( \varepsilon_{t+k} - \varepsilon_{t+k+1}^2 - \varepsilon_{t+k-1}^2 - \varepsilon_{t+k}^2 \right).
\]

Substituting from de Jong (1997, Lemma 3), we have

\[
\|X_{t+1} - X_t\|^2 \leq \sum_{k=-\infty}^{0} \left( \varepsilon_{t+k}^2 - \varepsilon_{t+k+1}^2 \right)^{1/2} \left( \varepsilon_{t+j,k+1}^2 - \varepsilon_{t+j,k+1}^2 \right)^{1/2}
\]

\[
+ \sum_{k=1}^{\infty} \left( \varepsilon_{t+k}^2 - \varepsilon_{t+k-1}^2 \right)^{1/2} \left( \varepsilon_{t+j,k-1}^2 - \varepsilon_{t+j,k-1}^2 \right)^{1/2}
\]

where on the assumptions, \( \varepsilon_{t+k} \leq c_{\text{mt}} \phi(k) \) for \( k \geq 0 \), and \( \varepsilon_{t+k} \leq c_{\text{mt}} \phi(k+1) \) for \( k \geq 0 \), where the numbers \( \phi(k) \) are from the mixingale definition. Therefore,

\[
\|X_{t+1} - X_t\|^2 \leq \sum_{k=1}^{\infty} \left( \varepsilon_{t+k}^2 - \varepsilon_{t+k+1}^2 \right)^{1/2} \left( \varepsilon_{t+j,k+1}^2 - \varepsilon_{t+j,k+1}^2 \right)^{1/2}
\]

\[
\leq 2T_{n1} + 2T_{n2}
\]

where

\[
T_{n1} = \sum_{k=1}^{\infty} \frac{n}{n} \left( \varepsilon_{t+k}^2 - \varepsilon_{t+k+1}^2 \right)^{1/2} \sum_{j=0}^{n-t} (1 - k(j / \gamma_0)) \left( \varepsilon_{t+j,k+1}^2 - \varepsilon_{t+j,k+1}^2 \right)^{1/2}
\]

and

\[
T_{n2} = \sum_{k=1}^{\infty} \frac{n}{n} \left( \varepsilon_{t+k}^2 - \varepsilon_{t+k+1}^2 \right)^{1/2} \sum_{j=0}^{n-t} (1 - k(j / \gamma_0)) \left( \varepsilon_{t+j,k-1}^2 - \varepsilon_{t+j,k-1}^2 \right)^{1/2}
\]

Take \( T_{n2} \) as representative. Define a summable sequence \( (\beta_m)_{m=0}^{\infty} \) by setting \( \beta_0 = 1 \) and \( \beta_m = m^{-1} \log(m+1)^{-2} \) for \( m \geq 1 \). Two applications of the Cauchy-Schwarz inequality yield

\[
T_{n2} \leq \sum_{k=1}^{\infty} \left( \varepsilon_{t+k}^2 - \varepsilon_{t+k+1}^2 \right)^{1/2}
\]

\[
\times \left( \sum_{t=1}^{n-t} (1 - k(j / \gamma_0)) \left( \beta_{j-1}^{-1/2} \varepsilon_{t+j,k-1}^2 - \varepsilon_{t+j,k-1}^2 \right)^{1/2} \right)^2
\]

\[
\leq \sum_{k=1}^{\infty} \left( \varepsilon_{t+k}^2 - \varepsilon_{t+k+1}^2 \right)^{1/2}
\]

\[
\times \left( \sum_{t=1}^{n-t} \beta_{j-1}^{-1/2} \left( \varepsilon_{t+j,k-1}^2 - \varepsilon_{t+j,k-1}^2 \right) \right) \sum_{j=0}^{n-t} (1 - k(j / \gamma_0))^2^{1/2}.
\]
Note that for any array \((h_{ij}), \sum_{i=0}^{n-1} \sum_{j=0}^{n-1} h_{i+r,j} = \sum_{i=0}^{n-1} \sum_{j=0}^{n-1} h_{ij}\), and therefore in particular

\[
\sum_{t=1}^{n} \sum_{j=0}^{n-t} \beta_j^{-1}(\xi_{2,i+j,k+1} - \xi_{2,i+j,k+2})
\]

by assumption. Therefore,

\[
T_{nk} = O \left( \sum_{k=1}^{n} \left( \sum_{t=1}^{n} (\xi_{2,t}^2 - \xi_{2,t+1}^2) \right)^{1/2} \right) = o(1)
\]

where it is used that \(\lim_{n \to \infty} \gamma_n^{-1} = 0\) and \(k(0) = 1\). This concludes the proof.

**Proof of Theorem 2.2:** In view of Theorem 2.1, the result follows if \(|\hat{\Omega}_n(\theta) - \hat{\Omega}_n| \to 0\). Define the \(r\)-vector

\[
W_{nk}(\theta) = \kappa_n^{-1} \frac{\partial X_{nk}}{\partial \theta}.
\]

Also define

\[
f_n(\theta_1, \theta_2) = \sum_{t=1}^{n} \sum_{s=1}^{n} X_{nk}(\theta_1) X_{nk}(\theta_2) k((t-s)/\gamma_n)
\]

such that \(\hat{\Omega}_n(\theta) = f_n(\theta, \theta)\). First-order Taylor’s expansions around \(\theta_0\), successively of \(f_n\), with respect to \(\theta_1\), and then of \(f_n\) and \(\partial f_n / \partial \theta_1\) with respect to \(\theta_2\), yield

\[
\hat{\Omega}_n(\theta_0) - \hat{\Omega}_n = 2 \sum_{t=1}^{n} \sum_{s=1}^{n} (\hat{\theta}_0 - \theta_0)^' \kappa_n W_{nk} X_{nk} \left( \frac{t-s}{\gamma_n} \right)
\]

where \(\hat{\theta}_0\) represents \(\theta_0\) with its elements evaluated at unspecified points (in general different in each term) on the line segment joining \(\theta_0\) and \(\hat{\theta}_0\). The last term here converges in probability to zero because \(n^{1/2}\kappa_n(\hat{\theta}_0 - \theta_0) = O_p(1)\) by assumption, and for \(n\) large enough,

\[
\left\| \sum_{t=1}^{n} \sum_{s=1}^{n} \lambda W_{nk} W_{nk} A \left( \frac{t-s}{\gamma_n} \right) \right\|_2 \leq n^{-1} \sum_{j=-n}^{n} \left[ k \left( \frac{j}{\gamma_n} \right) \left( \sum_{t=1}^{n} \sup_{\theta \in \mathbb{N}} |\lambda W_{nk}(\theta)| \right)^2 \right] = O \left( n^{-1} \sum_{j=-n}^{n} |k(j/\gamma_n)| \right) = o(1)
\]

for any \(\lambda \neq 0\), by assumption. Note that consistency of \(\hat{\theta}_0\) implies that the inequality holds for any \(\mathbb{N}\), with \(n\) large enough.
To show that the first term of (A-48) also converges in probability to zero, suppose first that Assumption 4(i) holds. Letting $W_{nt}$ denote $W_{nt}(\theta_0)$, note that

\[
(A-50) \quad \sum_{t=1}^{n} \sum_{s=1}^{n} (\hat{\theta} - \theta_0)' \kappa_{\gamma} W_{nt} X_{ns} k \left( \frac{t-s}{\gamma_n} \right) 
\]

\[
= \sum_{t=1}^{n} \sum_{s=1}^{n} (\hat{\theta} - \theta_0)' \kappa_{\gamma}(W_{nt} - EW_{nt}) X_{ns} k \left( \frac{t-s}{\gamma_n} \right) 
\]

\[
+ \sum_{t=1}^{n} \sum_{s=1}^{n} (\hat{\theta} - \theta_0)' \kappa_{\gamma} EW_{nt} X_{ns} k \left( \frac{t-s}{\gamma_n} \right). 
\]

The first term of (A-50) converges in probability to zero because $n^{-1/2} \kappa_{\gamma}(\hat{\theta} - \theta_0) = O_p(1)$ and

\[
(A-51) \quad \left\| n^{-1/2} \sum_{t=1}^{n} \sum_{s=1}^{n} \lambda'(W_{nt} - EW_{nt}) X_{ns} k \left( \frac{t-s}{\gamma_n} \right) \right\| 
\]

\[
\leq \int_{-\infty}^{\infty} \left\| n^{-1/2} \sum_{t=1}^{n} X_{nt} e^{-i\xi t/\gamma_n} \lambda'(W_{nt} - EW_{nt}) e^{i\xi t/\gamma_n} \right\| d\xi 
\]

\[
\leq \int_{-\infty}^{\infty} \left\| n^{-1/2} \sum_{t=1}^{n} X_{nt} e^{i\xi t/\gamma_n} \right\| \left\| \left( \sup_{\xi \in \mathbb{N}} n^{-1/2} \sum_{t=1}^{n} \alpha'(W_{nt} - EW_{nt}) e^{i\xi t/\gamma_n} \right) \right\| d\xi 
\]

\[
= o(1) 
\]

for any $\lambda \neq 0$, by assumption. Also,

\[
(A-52) \quad \left( \sum_{t=1}^{n} \sum_{s=1}^{n} (\hat{\theta}_n - \theta_0)' \kappa_{\gamma} EW_{nt} X_{ns} k \left( \frac{t-s}{\gamma_n} \right) \right)^2 = n(\hat{\theta}_n - \theta_0)' \kappa_{\gamma} M_n \kappa_{\gamma}(\hat{\theta}_n - \theta_0) 
\]

where

\[
(A-53) \quad M_n = n^{-1} \sum_{t=1}^{n} \sum_{s=1}^{n} \sum_{i=1}^{n} \sum_{j=1}^{n} EW_{ni} EW_{nj} X_{ns} X_{nt} k \left( \frac{t-s}{\gamma_n} \right) k \left( \frac{i-j}{\gamma_n} \right). 
\]

Since $M_n$ is a positive semidefinite matrix, the result now follows if we can show that $\lambda'M_n \lambda \to 0$ for any $\lambda \neq 0$. To prove this, first note that from the proof of Lemma A.5,

\[
(A-54) \quad \left| \sum_{i=1}^{n} \sum_{j=1}^{n} \sum_{s=1}^{n} \sum_{t=1}^{n} X_{ni} X_{nj} a_{nt} a_{ns} \right| = O \left( \left( \sum_{i=1}^{n} c_{t}^2 s_{ni}^2 \sum_{i=1}^{n} c_{t}^2 s_{nt}^2 \right)^{1/2} \right) 
\]

for $L_2$-mixingale random variables $X_{nt}$ of size $1/2$, and any deterministic array $a_{nt}$. Therefore, under the assumptions,

\[
(A-55) \quad \lambda'M_n \lambda = C \sum_{i=1}^{n} \left| \lambda'E W_{nt} \right| \left( n^{-2} \sum_{i=1}^{n} c_{t}^2 s_{ni}^2 \right)^{1/2} \sum_{i=1}^{n} c_{t}^2 s_{ni}^2 \left( \frac{t-s}{\gamma_n} \right)^2 
\]

\[
= C \left( \sum_{i=1}^{n} \left| \lambda'E W_{nt} \right| \left( n^{-1} \sum_{s=1}^{n} c_{t}^2 s_{ni}^2 \right) \left( \frac{t-s}{\gamma_n} \right)^2 \right)^{1/2} 
\]

\[
\leq C \left( \sum_{i=1}^{n} \left| \lambda'E W_{nt} \right|^2 \left( n^{-1} \sum_{s=1}^{n} c_{t}^2 s_{ni}^2 \sum_{t=1}^{n} k \left( \frac{t-s}{\gamma_n} \right)^2 \right) \right) 
\]

\[
= O \left( \frac{\gamma_n}{n} \right) = o(1). 
\]
for $C > 0$, where the second inequality follows from the Cauchy-Schwarz inequality.

Now suppose that Assumption 4(iii) holds. In this case we may argue similarly to Hansen’s (1992, p. 971) inequality (A4), except that we replace Hansen’s $\delta_x X_1$ by $W_n$, to argue that

$$\sum_{t=1}^{\infty} \sum_{s=1}^{n} (\theta_t - \theta_0)^r X_{nt} k \left( \frac{t-s}{\eta} \right) = O_p(n^{-1/2} \eta) = o_p(1).$$

This concludes the proof.

Q. E. D.

**Proof of Theorem 2.3:** By assumption, $\hat{\theta}$ can be made an element of the interval $[\epsilon, 1/\epsilon]$ for some small $\epsilon \in (0, 1)$ with arbitrarily large probability. Furthermore it is well-known (see, e.g., Newey (1991)) that

$$\sup_{\theta \in [\epsilon, 1/\epsilon]} |\hat{\theta}_n(\theta, \alpha, \gamma) - \theta_n| \rightarrow 0$$

if $|\hat{\theta}_n(\theta, \alpha, \gamma) - \theta_n|$ converges to zero pointwise in $\alpha$ and $\hat{\theta}_n(\theta, \alpha, \gamma) - \theta_n$ is stochastically equicontinuous on $[\epsilon, 1/\epsilon]$. Pointwise convergence follows from the results that were established earlier. Stochastic equicontinuity follows if both of the terms $\hat{\theta}_n(\theta, \alpha, \gamma) - \theta_n$ and $\hat{\theta}_n(\theta, \alpha, \gamma) - \theta_n$ are stochastically equicontinuous on $[\epsilon, 1/\epsilon]$. The first of these results follows because

$$\sup_{\theta \in [\epsilon, 1/\epsilon]} \sup_{\alpha \in [\epsilon, 1/\epsilon]} |\hat{\theta}_n(\theta, \alpha, \gamma) - \theta_n| \rightarrow 0,$$

so

$$\sup_{\theta \in [\epsilon, 1/\epsilon]} \sup_{\alpha \in [\epsilon, 1/\epsilon]} \sup_{\gamma \in [\epsilon, 1/\epsilon]} |\hat{\theta}_n(\theta, \alpha, \gamma) - \theta_n| \rightarrow 0.$$

Therefore, using Lemma A.1 again, it is easily seen that

$$\lim_{\eta \rightarrow 0} \sup_{\alpha \in [\epsilon, 1/\epsilon]} \sup_{\gamma \in [\epsilon, 1/\epsilon]} |\hat{\theta}_n(\theta, \alpha, \gamma) - \theta_n| = 0,$$

which implies stochastic equicontinuity of $\hat{\theta}_n(\theta, \alpha, \gamma) - \theta_n$. To show the second result, consider
equation (A-48). By the reasoning leading up to equation (A-49), it is easily shown that

\begin{equation}
\sup_{a \in [e, 1/e]} \left\| n^{-1} \sum_{t=1}^{n} \sum_{s=1}^{n} W_{nt} \hat{W}_{nt} k \left( \frac{t-s}{\alpha r_n} \right) \right\| = O \left( n^{-1} \sum_{j=-n+1}^{n-1} \sup_{a \in [e, 1/e]} \left\| k \left( \frac{j}{\alpha r_n} \right) \right\| \right)
\end{equation}

by assumption, where \( W_{nt} \) is defined as before. Therefore, for proving stochastic equicontinuity of

\begin{equation}
\sup_{n \rightarrow \infty} \left\| n^{-1} \sum_{t=1}^{n} \sum_{s=1}^{n} W_{nt} \hat{W}_{nt} k \left( \frac{t-s}{\alpha r_n} \right) \right\| = o(1)
\end{equation}

\( \text{REFERENCES} \)
