Chapter 8

Trends in Income Support

John Karl Scholz, Robert Moffitt, and Benjamin Cowan

Antipoverty programs are designed to mitigate the most pernicious aspects of market-based economic outcomes—unemployment, disability, low earnings, and other material hardship. These programs compose society's "safety net," and each has different eligibility standards and benefit formulas. While the programs can be aggregated and categorized to summarize trends in coverage and generosity, a consequence of their patchwork nature is that the safety net may appear different to a family in one set of circumstances than it does to a family in another.

Social insurance programs—Social Security, Medicare, unemployment insurance, and workers' compensation—are costly programs with much larger numbers of recipients. Despite the fact that they are not antipoverty programs per se, they have had a significant effect on poverty, particularly among the elderly. The antipoverty programs that constitute the safety net are collectively much smaller and have had varied support over time.

As noted in previous work (Burtless 1986, 1994; Scholz and Levine 2002), there has been a sharp reduction in cash entitlements for poor families and a very large increase in social insurance payments, particularly for the elderly, in past decades. The nature of programs has changed as well. Cash welfare benefits, for example, have been linked with work requirements, partly in response to evolving views about the nature of the poverty problem. Responsibility for antipoverty policy has broadened from the antipoverty agencies of the federal government (the Department of Health and Human Services and the Department of Labor) to the states (through their administration of Temporary Assistance for Needy Families [TANF] and Medicaid) and the tax code, as evidenced by the Earned Income Tax Credit (EITC) and the refundable child credit.

We have three primary goals in this chapter. First, we provide updated information on expenditures and recipients for a range of antipoverty programs, describing the evolution of the safety net over the past thirty-five years. Second, we use data from the Survey of Income and Program Participation (SIPP) to calculate the antipoverty effectiveness of federal programs for families and individuals in different circumstances. Third, we explore changes in the characteristics of recipients of means-tested transfers, tax credits, and social insurance. Robert Moffitt (2003a,

2007) documents a large increase in total per capita means-tested transfers, even in the decade following the 1996 welfare reform. He notes, based on aggregate data, that the shift in expenditures for different programs suggests that more transfers now go to workers and fewer to nonworkers, more to married couples and fewer to single mothers. Because aggregate transfers have increased, one can argue that society has become more generous over time. But as the safety net has evolved, some families have lost benefits while others have gained benefits.

SOCIAL INSURANCE

Social insurance programs provide near-universal coverage since any individual (or his or her employer) who makes the required contributions to finance the programs can receive benefits when specific eligibility requirements are met. These programs have dedicated funding mechanisms through which, at least in an accounting sense, social insurance taxes are remitted to trust funds from which benefits are paid.

It is often inefficient for individuals to self-insure for contingencies like an unexpectedly long life, end-of-life health shocks, or extended unemployment spells. Because of adverse selection problems—the tendency for the riskiest individuals and families to seek insurance, which makes the pricing of products unattractive to less risky families and individuals—private insurance markets are unlikely to work well. Social insurance programs, which are government-run, near-universal, and uniform in their rules and benefits, provide the welfareenhancing benefits of insurance while overcoming the problems (through mandatory pooling) that arise in private insurance markets.

Social Security and Medicare

The largest social insurance program is Social Security, formally known as the Old-Age, Survivors, and Disability Insurance (OASDI) program. Founded in 1935 as one of President Franklin Roosevelt's New Deal programs, Social Security was designed to meet the unmet social needs of older workers leaving the workforce without sufficient postretirement income to be self-supporting.¹ Figure 8.1 plots the time series of real (inflation-adjusted) Social Security (OASI) payments from 1970 to 2006. (Disability insurance benefits are not included in this series but are discussed later.) Real Social Security payments tripled between 1970 and 2006, to \$474 billion, because of three factors. First, the number of retired workers covered by Social Security has steadily increased as the aged population has grown over the years and state and local government workers, clergy, and other groups have been brought into the system. Second, the Social Security taxable wage base has grown steadily, as have real earnings. Third, legislated benefit increases frequently exceeded the cost of living into the early 1970s; benefits were indexed to inflation beginning in 1974. Aggregate real Social Security benefits increased 5.6 percent annually in the 1970s and 3.0 percent in the 1980s. Aggregate annual real benefits increased 1.8 percent in the 1990s and by the same amount between 2000 and 2006.

Because many retired elderly workers have little labor market and capital income, pre–tax and transfer poor families receive a substantial share of Social Security benefits. The official poverty rate for people age sixty-five and older was 9.4 percent in 2006.² It was 17.4 percent for children under age eighteen, and 12.3 percent for all persons. The elderly poverty rate is the lowest largely because of Social Security benefits, which averaged \$11,566.³

The elderly also receive substantial benefits from Medicare, which provides hospital insurance and supplementary medical and prescription drug coverage for most people over age sixty-five and for most Social Security disability recipients under age sixty-five.⁴ Real Medicare outlays increased more than tenfold from \$41 billion in 1970 (the program started in 1967) to \$413 billion in 2006. Real expenditures per Medicare enrollee increased almost five times over the same time period, to \$9,378 in 2006. In the late 1990s and early 2000s, Medicare growth slowed as efforts were made to reduce Medicare hospital spending and control fraud and abuse. Spending increased sharply in 2006 with the implementation of Medicare Part D, a prescription drug benefit that is projected to cost more than \$40 billion annually.

A substantial portion of Medicare benefits go to elderly families whose pretransfer incomes are below the poverty line. The official poverty measure does not account for Medicare benefits because they are in-kind (via the provision of health care and insurance) rather than in the form of cash. Hence, Medicare benefits are difficult to value. They could be valued at their cost to the government, at the cost a recipient would have to pay in the private market to acquire comparable benefits, or at the amount a person would be willing to pay for such benefits (which would be less than the cost to the government for many low-income recipients).⁵ It is also difficult to determine which individuals in a given family receive benefits. In this chapter, when we assess the antipoverty effectiveness of spending, we make illustrative calculations of the degree to which Medicare reduces poverty.

The effect of Social Security on poverty is clear: as the Social Security system has grown, elderly poverty has fallen precipitously. The sharpest decline in the elderly poverty rate occurred between 1959 and 1974, a period that coincides with rapid growth in Social Security spending.⁶

Social Insurance for Prime-Age Workers

Although Social Security and Medicare also provide benefits for non-elderly people through disability insurance (DI) and survivor benefits, 84.7 percent of Medicare recipients were elderly in 2004 and 71.9 percent of Social Security recipients were elderly in March 2008.⁷ Three smaller social insurance programs—unemployment insurance (UI), workers' compensation, and disability insurance—target prime-age workers; real expenditures on these programs are also shown in figure 8.1.

Unemployment insurance is a state-level program that provides temporary and partial wage replacement to workers who become involuntarily unemployed and who have a recent history of continuous employment at moderately high wages.⁸ Although UI allows families to maintain their consumption during periods of involuntary layoffs (Gruber 1997), it has relatively small antipoverty effects because so many unskilled individuals do not have the necessary employment history at high enough wages to collect UI benefits. The Government Accountability Office (GAO 2000) reports that in the 1990s low-wage workers were twice as likely to be unemployed but less than half as likely to receive UI benefits as other unemployed workers.⁹ Unemployment insurance is highly cyclical. Real UI benefits paid out in 2003, a year of slow economic growth, came to \$61 billion, while real payments were \$25 billion in 2000, a year with low unemployment.

Workers' compensation is a state-level program that provides cash and medical benefits to some persons with job-related disabilities or injuries and provides survivor benefits to dependents of workers whose death resulted from a work-related accident or illness. Benefit levels vary widely across states. Workers' compensation payments were \$59 billion in real terms in 2005; Bruce Meyer, Wallace Mok, and James Sullivan (2007) note that roughly half of total program costs are for medical care. Because there is little federal involvement in this system, there is little information on its antipoverty effects. We speculate that any such effects are likely to be small, however, for the same reasons that UI has limited antipoverty effectiveness.

Disability insurance, a federal program that is part of the Social Security program, provides benefits when a covered worker is unable to engage in "substantial

gainful activity" by reason of a physical or mental impairment that is expected to last for more than twelve months or that results in death.¹⁰ Workers must have a minimum period of covered employment before being eligible; depending on the age at which a disability occurs, this ranges from six to forty covered quarters. The average annual growth rate in real DI expenditures was 9.0 percent in the 1970s, 0.1 percent in the 1980s, 5.3 percent in the 1990s, and 6.2 percent between 2000 and 2006. Despite program growth, the DI rules are stringent, with fewer than 40 percent of all applications being granted benefits; roughly 5.4 awards are made per 1,000 covered workers. Around 8.6 million people (including children) receive disability benefits, which cost \$95 billion in 2006. Most DI recipients are pre-tax and transfer poor.¹¹

Summary of Social Insurance

Social Security, Medicare, unemployment insurance, workers' compensation, and disability insurance are the major social insurance programs. Over time, the enormous increase in their benefits has been driven largely by increases in Social Security and Medicare. Social insurance benefits are predicated on events that are salient for most Americans—retirement, unemployment, a disability or work-related injury and receipt of benefits does not depend on an individual's current total income but rather on past employment and earnings experience. All have dedicated financing mechanisms. And while Social Security may reduce national saving and hasten retirement, and while unemployment insurance may alter the intensity with which the unemployed search for jobs, there is no evidence that these programs encourage individuals not to marry or to have children out of wedlock, and with the possible exception of DI, they do not encourage individuals to spend extended periods out of the paid labor market (UI benefits are time-limited). Thus, the rationale and incentives of the programs do not appear at odds with societal norms of personal responsibility. In addition, Social Security and Medicare lessen adult children's caregiving responsibilities for their parents, a feature that is popular with both generations.

MEANS-TESTED TRANSFERS

Means-tested programs are financed by general tax revenues rather than through dedicated financing mechanisms; all limit benefits to those whose incomes and/or assets fall below some threshold. Some are entitlements—all who satisfy the stipulated eligibility requirements receive benefits, regardless of the total budgetary cost (for example, Medicaid, food stamps). Other means-tested programs provide benefits only until the funds that Congress or a state has allocated are spent, even if some eligible participants are not served (for example, the State Children's Health Insurance Program [SCHIP], Section 8 housing vouchers, and TANF). Means-tested programs have explicit antipoverty goals. Together, they account for a smaller share of government budgets than the social insurance programs.

Source: Refer to source notes for figure 8.1.

Health Care and the Disabled

Medicaid, the largest means-tested transfer program (Swartz, this volume), funds medical assistance to persons who are aged, blind, or disabled and to certain pregnant women and dependent children. Recipients must meet asset and income tests that are set by states. Medicaid was expanded between 1986 and 1991 as Congress required states to cover pregnant women and children living in families with incomes up to 133 percent of the poverty level and allowed the expansion of coverage to families with incomes of up to 185 percent of the poverty level.¹² These expansions led to a large increase in the number of Medicaid recipients. About 23 million people received Medicaid in 1977 and 1988, but this number climbed steadily to 55 million in 2004. About 10 percent of Medicaid beneficiaries were sixty-five or older in 2005; they received about 26 percent of Medicaid expenditures.

The trend in Medicaid spending is shown in figure 8.2. Total real Medicaid spending increased from \$28 billion to \$320 billion between 1970 and 2006. After growing rapidly through the mid-1970s, Medicaid grew at annual rates between -0.5 percent and 8.8 percent between 1976 and 1989. The expansions of the late 1980s increased growth rates to 12.8, 21.4, and 12.1 percent in 1990, 1991, and 1992. Spending fell in 2006, owing largely to shifts in prescription drug costs to Medicare

Part D and to a reduction in the growth of enrollments (Holahan, Cohen, and Rousseau 2007; Swartz, this volume). Attempts to assess the antipoverty effectiveness of Medicaid face the same difficulties that arise with valuing Medicare benefits: it is not clear whether Medicaid benefits should be valued at the cost to the recipient, at the cost a recipient would have to pay in the private market to obtain similar benefits, or at the amount a person would be "willing to pay," which itself is difficult to know.

Supplemental Security Income (SSI) is a means-tested, federally administered, cash assistance program for the aged, blind, and disabled. The disabled make up nearly 80 percent of recipients. The program began in 1974 with the consolidation of several smaller programs.¹³ An individual who meets the income, asset, and categorical eligibility standards receives a cash transfer of up to \$637 per month; couples can receive up to one and a half times that amount, and children can receive half that amount, although states are allowed to supplement these amounts. SSI (figure 8.2) grew very slowly, from \$22 billion to \$26 billion, between 1974 and 1990 (in 2007 dollars).

Between 1990 and 1994, SSI costs grew by 55 percent, making it one of the fastest-growing entitlement programs. A factor driving this growth was the Zebley decision, a Supreme Court case that revised the childhood mental health impairment eligibility criterion to be consistent with the criterion that applies to adults. The Green Book (1998) reports that three groups accounted for nearly 90 percent of SSI's growth during this time: adults with mental impairments, children, and noncitizens. Since the mid-1990s, efforts have been made to reduce the growth in the number of children and immigrants covered by SSI, so real spending in 2006 was roughly equal to spending in 1994. In 2006, 7.2 million people received \$40 billion in benefits.

Cash Means-Tested Transfers for Able-Bodied Families

Aid to Families with Dependent Children (AFDC) was the central safety net program for poor families with children from 1936 to 1996 (Moffitt 2003b). This program was directed primarily at single-parent families, though some two-parent families with an unemployed parent received benefits. AFDC was a means-tested entitlement, meaning that all applicants whose income and assets were below the stipulated levels could receive benefits. State-determined benefit generosity varied widely; funds were provided according to an uncapped federal matching formula.

The Personal Responsibility and Work Opportunity Reconciliation Act (PRWORA) of 1996 abolished AFDC and created Temporary Assistance for Needy Families (TANF), which provides block grants to states with few restrictions. States are required to spend at least 75 percent of their "historic" level of AFDC spending; a five-year lifetime limit has been imposed on receipt of federally supported cash assistance, though some hardship exemptions are allowed; and states have to meet targets for moving recipients into work activities. A combination of these AFDC-TANF changes, the longest economic expansion in history, sharp

FIGURE 8.3 / Total AFDC-TANF and EITC Benefits, 1970 to 2007 (in Constant 2007 Dollars)

Source: Refer to source notes for figure 8.1.

increases in the Earned Income Tax Credit, and other factors contributed to a 52 percent decline in welfare caseloads between January 1993 and December 1999. Despite the weak economy in the years after the recession in 2001, TANF case-loads did not increase substantially from their historic lows.

Several commentators feared that TANF might set off a "race to the bottom" that is, that the states, fearful of attracting low-income families from other states, might lower benefits, causing other states, in turn, to lower theirs. In fact, total AFDC-TANF spending on cash benefits declined from a peak of about \$40 billion in 1995 to about \$20 billion in 2006 (figure 8.3), but this reduction is roughly proportional to the welfare caseload reduction. In some jurisdictions, spending on other ancillary services for welfare recipients and other low-income families (for example, child care and transportation) has also increased since the mid-1990s.

The Deficit Reduction Act (DRA) of 2005 reauthorized the TANF program and increased work requirements—50 percent of all adults in single-parent families receiving TANF benefits in a state and 90 percent of the two-parent households receiving such benefits must now work. These percentages are lower for states if their welfare caseloads fall below 2005 levels, but caseloads in that year were at historically low levels, so this provision is unlikely to relax substantially the work requirement constraint. It is likely that states will place even greater emphasis on increasing employment among TANF recipients, divert potential TANF applicants from the program, or both.

Real spending on AFDC-TANF grew by an annual rate of 0.3 percent in the 1980s and fell by 2.5 percent in the 1990s. It fell by 4.2 percent a year from 2000 to 2005, despite a weak economy. In contrast, expenditures on the EITC grew sharply, from \$5 billion in 1975 to \$45 billion in 2006 (figure 8.3).¹⁴ Most of this growth occurred after 1987; real EITC expenditures grew at an annual rate of 9.1 percent in the 1980s (owing to legislated increases in 1986), 12.5 percent in the 1990s (owing to legislated increases in 1986), and 3.0 percent from 2000 to 2005. No other federal antipoverty program has grown so rapidly since the mid-1980s. The EITC is now the nation's largest cash or near-cash antipoverty program.

The incentives embedded in the EITC differ from those in AFDC-TANF. AFDC recipients with no earnings received the largest welfare payments. In contrast, the EITC encourages low-skilled workers to enter the labor market, since non-earners do not receive the credit, and the EITC amount rises with earnings up to about the poverty line.

A child tax credit was created in the 1997 Taxpayer Relief Act. Until 2001, the credit provided little financial benefit for poor and near-poor families because of limits on its refundability. Beginning in 2002, the child credit was made at least partially refundable for taxpayers with children and with earned income exceeding \$10,750 (indexed for inflation). In 2004, a year we focus on later, the credit was a maximum of \$1,000 per child. For taxpayers with no other federal income tax liability, 10¢ of child credit is paid (as a refundable credit) for every dollar earned in excess of \$10,750, up to the total available child credit.

In-Kind Means-Tested Transfers for Able-Bodied Individuals

The safety net for low-income families includes in-kind benefit programs, the largest of which are food stamps, housing assistance, Head Start, school nutrition programs, and the special supplemental nutrition program for women, infants, and children (WIC).¹⁵ The evolution of expenditures for these programs is shown in figure 8.4.

Food stamps are designed to enable low-income households to purchase a nutritionally adequate low-cost diet. It is the single, almost-universal entitlement for those with low income and assets. The maximum monthly food stamp benefit for a family of four was \$542 in 2008.¹⁶

After food stamp benefits were made uniform across the country and indexed for inflation in 1972, real spending grew sharply. Legislative changes in 1981 and 1982 cut spending between 1982 and 1985 by nearly 13 percent (\$7 billion) below what would have been spent under prior law. The liberalization of the program in 1985, 1986, and 1987, together with the early 1990s recession, led to a sharp increase in total food stamp spending between 1988 and 1992. Between 1994 and 2000, real food stamp expenditures fell to \$18 billion from \$32 billion, even though only modest changes to food stamp program rules were made by the 1996 welfare reform (primarily affecting immigrant households). The General Accounting Office (1999) concluded that participation fell "faster than related economic indicators

FIGURE 8.4 / Total Benefits or Program Costs for Various In-Kind Programs, 1970 to 2007 (in Constant 2007 Dollars)

Source: Refer to source notes for figure 8.1.

would predict" and speculated that some former cash welfare recipients thought they were also no longer eligible for food stamps.

Food stamp participation and spending increased sharply between 2000 and 2005: the caseload increased from around 18 million to 30 million, and spending increased from \$18 billion to \$31 billion (Rosenbaum 2006). Factors affecting these developments include increases in the number of poor people over this period, the use of food stamps as federal disaster aid for Hurricanes Katrina, Rita, and Wilma and other natural disasters, and changes in the 2002 farm bill that restored food stamp benefits to some legal immigrants, allowed states to provide benefits to households that own a reliable car, and simplified application procedures.

The Department of Housing and Urban Development (HUD) is primarily responsible for safety net housing assistance programs. Because these programs have never been entitlements, waiting lists are common. Aid comes in two principal forms: project-based aid (subsidies are tied to units constructed for low-income households) and household-based subsidies (renters choose housing units in the existing private housing stock). Since 1982, project-based aid has been curtailed in favor of rental subsidies. Housing assistance grew from \$3 billion in 1970 (in 2007 dollars) to \$37 billion in 1995, and then fluctuated, reaching \$39 billion in 2007 (figure 8.4). The number of housing assistance recipients rose from 3.2 million in 1997 to a peak of 5.8 million in 1995, before declining to 5.1 million in 2007. Federal housing subsidies provide roughly \$7,720 in annual benefits per recipient.

The school lunch and breakfast programs—entitlements funded by the Department of Agriculture—provide federal support for meals served by public and private nonprofit elementary and secondary schools and residential child care institutions that enroll and offer free or reduced-price meals to low-income children. Participation in the school breakfast program grew from about 800,000 in 1971 to 10 million in 2007. The school lunch program is larger but has grown more gradually, from 24 million children in 1971 to 31 million in 2007. Combined expenditures in 2007 were around \$11 billion.

The special supplemental nutrition program for women, infants and children (WIC) provides vouchers for food purchase, supplemental food, and nutritionrisk screening and related nutrition-oriented services to low-income pregnant women and low-income women and their children (up to age five). WIC is not an entitlement. In 2007 roughly 8 million women, infants, and children received benefits from WIC, at a cost of almost \$6 billion.

Head Start, an early childhood education program launched as part of the War on Poverty, seeks to improve social competence, learning skills, and the health and nutrition status of low-income children so that they can begin school on an equal basis with their more advantaged peers (Jacob and Ludwig, this volume). In real dollars, Head Start grew at an annual 9.9 percent rate in the 1990s. Program growth slowed considerably between 2000 and 2006, averaging 1.6 percent. Spending in 2006 was \$7 billion for around 900,000 children.

Child Care

Several federal child care subsidy programs target low-income families. Because child care expenses are often seen as a deterrent to mothers entering the workforce (Waldfogel, this volume), the emergence of child care subsidy programs reflects the trend toward work-based assistance rather than cash welfare (Blau 2003). In 1988 the Family Support Act created the Aid to Families with Dependent Children Child Care, which served AFDC parents who participated in job training, and Transitional Child Care, which served former welfare recipients.¹⁷ Two more programs were implemented in 1990: At-Risk Child Care, which served families at risk of going on welfare, and the Child Care Development Block Grant, which funds working, low-income families and provides funding to improve the quality of child care. In 1996 PRWORA consolidated all of these programs into the Child Care and Development Fund (CCDF).

According to Douglas Besharov, Caeli Higney, and Justus Myers (2007), the Child Care Development Block Grant more than doubled, from \$4 billion to about \$9 billion (in 2007 dollars), between 1996 and 2000, then rose to \$10 billion in 2005. After the 1996 welfare reform, states could spend TANF block grant money on child care; by 2000 they had spent \$3 billion. In 2005, 1.75 million children were served by the Child Care and Development Fund. The antipoverty effects of subsidized child care are not well known.

FIGURE 8.5 / Total Social Insurance, Cash, and In-Kind Means-Tested Transfers, 1970 to 2007 (in 2007 Dollars)

Source: Refer to source notes for figure 8.1.

Summary

Figure 8.5 summarizes the evolution of social insurance and means-tested (antipoverty) spending. Table 8A.1 presents spending by program, and table 8A.2 the numbers of recipients by program. Spending on all social insurance programs now exceeds \$1 trillion annually. These expenditures (in real dollars, excluding workers' compensation owing to data limitations) rose at an annual rate of 7.2 percent in the 1970s, 3.3 percent in the 1980s, 2.9 percent in the 1990s, and 4.3 percent (in part because of Medicare Part D) between 2000 and 2006.

The bottom two lines of figure 8.5 show total spending on in-kind transfers (without Medicaid) and cash transfers. Means-tested in-kind transfers (the sum of school nutrition programs, WIC, Head Start, housing assistance, and food stamps) grew at an annual rate of 16.0 percent in the 1970s, 2.1 percent in the 1980s, 2.0 percent in the 1990s, and 5.1 percent between 2000 and 2005.¹⁸ Means-tested cash transfers (the sum of AFDC-TANF, SSI, and the EITC) grew at an annual rate of 3.4 percent in the 1970s, 2.1 percent in the 1980s, and 4.2 percent in the 1990s, and they fell for the first time in thirty-five years between 2000 and 2005, despite a weak economy.

The growth rates of both cash and in-kind safety net spending increased significantly in the 1990s relative to the 1980s. In-kind programs continued to increase in the 2000s, while cash programs shrank. Spending on cash and in-kind antipoverty programs excluding Medicaid was around \$200 billion in 2005; Medicaid was an

additional \$333 billion. In the following section, we discuss the degree to which these programs alleviate poverty.

EFFECTS OF ANTIPOVERTY POLICIES

In this section, we address the complex question: how do the social insurance and means-tested programs we have described affect the poverty rate and the depth of poverty among poor people? We examine the antipoverty effectiveness of these programs by measuring the degree to which they reduce the aggregate poverty gap, which is defined as the sum of the differences between market income and the poverty line for all families with incomes below the poverty line.¹⁹ We measure the poverty gap using data from the first waves of the 1984, 1993, and 2004 Surveys of Income and Program Participation (SIPP), a nationally representative survey conducted by the U.S. Census Bureau. Each interview elicited information for the four months prior to the interview month. These surveys were conducted at similar business cycle points—October 1983 was eleven months, February 1993 twenty-three months, and February 2004 twenty-seven months following the trough of the prior recession.

We emphasize four questions. First, how large is the poverty gap, and how did it change between 1984 and 2004? Second, how has the antipoverty effectiveness of the tax and transfer system changed? Third, how effective are current programs in filling the poverty gap? And fourth, how do the effects of public policies differ across demographic groups—for example, among the elderly, one- and two-parent families, and families without children?

Behavioral Responses

Our analysis does not take into account behavioral responses to different programs, so before beginning our discussion of the preceding questions, we briefly discuss labor market, saving, and family formation responses to changes in the safety net for prime-age workers and their likely effect on our results.²⁰ These responses have been at the heart of the policy debates shaping the evolution of antipoverty policy.²¹ The rapid increase in the Earned Income Tax Credit since 1986, for example, reflects the fact that the credit is widely perceived as being "prowork." The momentum to "end welfare as we know it" in the early 1990s was fueled by a concern that AFDC had created a cycle of dependency, encouraging some women to not work and to have children.

All open-ended, means-tested transfer programs—that is, those that provide more benefits the lower the family income is—provide a disincentive to work because additional work necessarily reduces the benefits received. Economists have put most of their emphasis on the importance of the "tax rate" in these programs defined as the fraction of benefits lost as income rises—and have recommended that the tax rate be kept low to minimize work disincentives. Historically, tax rates have been very high for low-income families. For example, as Stacy Dickert, Scott Houser, and John Karl Scholz (1995) show, in 1990 cumulative *average* tax rates (that is, tax rates summed over all the programs in which a family participated) exceeded 85 percent for some low-wage, single-parent families from New York working anywhere from eight to thirty-five hours per week. This implies that an extra dollar of earnings would increase take-home income by only fifteen cents.

Since 1990, however, tax rates have been greatly reduced in the TANF program, and the EITC expansion has lowered them even further. Tax rates for those with very low earnings are usually less than 30 percent, and often they are negative (that is, benefits actually increase with earnings) because of the EITC (Coe et al. 1998).²² These tax rate reductions increased employment rates over the late 1980s and 1990s (Meyer and Rosenbaum 2001). A series of classical experiments testing the effect of increased financial incentives on the work effort of low-income families also showed that families respond positively to such incentives (Berlin 2000).

Savings among low-income families can also be affected by antipoverty programs because eligibility requires low income and assets, which means that families will lose eligibility if they save enough to exceed these levels. Glenn Hubbard, Jonathan Skinner, and Steven Zeldes (1995) construct a simulation model that predicts, in the absence of asset testing, that low-income families would save considerably more than they actually do in the presence of asset testing, regardless of whether they ever draw program benefits. Nevertheless, the empirical evidence that asset tests discourage wealth accumulation is scant, at least for prime-age individuals (Hurst and Ziliak 2006; Engelhardt et al. 2008).²³

Antipoverty programs often provide greater resources to single-parent families than to two-parent families and so may provide incentives to delay marriage, divorce, or not marry. Program benefits and the EITC also generally increase with family size and hence provide incentives to have additional children. Many studies have addressed the question of whether antipoverty programs affect behavior in the ways just described, and the results suggest that low-income individuals do indeed respond to these incentives, but that the magnitude of the response is small (Moffitt 1998).

We conclude that the tax and transfer system has measurable effects on the behavior of low-income families, with the strongest effects on reducing work effort. This implies that our estimates of the effect of antipoverty programs on the incomes of the poor, given later in the chapter, are overstatements of their initial impact, because those programs may cause incomes to fall even further as work effort is reduced. Our impact estimates should consequently be regarded as upper bounds.

The Evolution of the Poverty Gap, 1984 to 2004

Our market income measure aggregates wage and salary income, self-employment income, capital income (interest, dividends, and rents), and defined benefit pension income.²⁴ We do not consider the effects of the individual income tax, aside from the refundable EITC and child tax credits. Omitting the federal individual income tax has little consequence for poverty gap calculations because in recent years most poor families with children have not paid positive income taxes because of personal

Notes: Dollar amounts are in 2007 dollars, using the CPI-U. The transfers reflected in the calculations include those listed in table 8.2, except Medicare and Medicaid.

a. This poverty rate is for families and unrelated individuals: it reflects the fraction of families (including single-person "families") in poverty rather than the fraction of the total population in poverty; the latter is the more traditional measure, emphasized in other chapters of this volume.

and child exemptions and the standard deduction. Low-income taxpayers without children and with incomes near the poverty line pay small amounts of federal income taxes. In contrast, because all workers are subject to the payroll tax, we reduce reported earnings by 7.65 percent (the employee OASDI tax rate) when measuring the poverty gap and the percentage of the population who are poor.

We include the following programs in table 8.1, which shows the evolution of the poverty gap between 1984 and 2004: Social Security (OASDI), unemployment compensation, workers' compensation, SSI, AFDC-TANF, the EITC, the child tax credit, general assistance, other welfare, foster child payments, veterans' benefits, food stamps, WIC, and housing assistance.²⁵

SIPP and other nationally representative household surveys underreport aggregate transfers (Meyer, Mok, and Sullivan 2007). However, the number of recipients and the aggregate benefits for veterans' benefits, general assistance, other welfare, foster child payment, and OASI fairly closely match the administrative totals (or the programs are small, in cases where administrative totals are not readily available).²⁶ Because noncompliance biases the administrative totals for the EITC, we do not adjust our SIPP-based EITC calculations, nor do we adjust our child credit calculations in 2004. We do not have good administrative data on the number of worker's compensation recipients, so we adjust reported benefits in the SIPP to match the cash receipts reported in Meyer, Mok, and Sullivan (2007). For housing (and Medicaid in tables 8.2 and 8.3), we impute recipients based on the income, education, marital status, number of children, race-ethnicity, gender (of the family reference person), region, age (of the family reference person), age of children, and participation in other programs. In brief, we assign a propensity score to each nonrecipient SIPP household and impute average benefits to the nonrecipients with the highest probability of receiving benefits, until

24,493	908	60.6	37.5	70.9	6,227	479	14.3

we match the number of recipients in the administrative data. For AFDC-TANF, food stamps, WIC, disability insurance, SSI, and UI, we do the same, and then once we match the number of recipients in the administrative data, we adjust household benefits in the SIPP to match the aggregate benefits reported in the administrative data. Hence, for each program we consider, we (roughly) match both the number of recipients and aggregate (and average) benefits in the administrative data.

We exclude Medicare and Medicaid in table 8.1 for two reasons. First, it is technically difficult to estimate the value of Medicare and Medicaid. Second, medical benefits and insurance are only imperfectly fungible with other expenditures. Hence, if resources are not available for food, shelter, and clothing, it is not clear that it would be appropriate to suggest that the insurance value of health benefits is sufficient to move an otherwise poor family above the poverty line. We do value Medicare and Medicaid when we focus on the effects of specific programs in 2004 in tables 8.2 and 8.3.

All programs considered in table 8.1 deliver cash benefits, except for food stamps and housing benefits. Because the value of food stamps does not exceed the food needs of the typical family, we value them at the cost to the government. We use fair market rent (FMR) data from the Department of Housing and Urban Development and value in-kind housing benefits as the difference between rents paid by housing assistance recipients and the FMR in the state.²⁷

The first row of table 8.1 shows that the 2004 SIPP, when weighted, represented 124.5 million families (including unrelated individuals as one-person families). Using our after-payroll-tax, pretransfer income concept, 30.3 percent were poor. The pretransfer poverty gap, in 2007 dollars, was \$30.2 billion a month, or \$800 per poor family, suggesting that a perfectly targeted transfer of exactly that

TABLE 8.3 / Antipoverty Effectiveness of the Transfer System for Different Family Types, 2004 SIPP

Source: Authors' calculations from wave 1 of the 2004 SIPP (U.S. Bureau of the Census, various years). *Note:* Dollar amounts in 2007 dollars, using the CPI-U.

a. This poverty rate is for families and unrelated individuals: it reflects the fraction of families (including single-person "families") in poverty rather than the fraction of the total population in poverty; the latter is the more traditional measure, emphasized in other chapters of this volume.

amount could have eradicated poverty, assuming no other behavioral responses. Total transfers measured in SIPP (excluding Medicare and Medicaid) were \$65.0 billion per month, or \$844 per recipient family; of these transfers, 54.0 percent were received by pretransfer poor families and 30.7 percent reduced the poverty gap.²⁸ The tax and transfer system closed 66.2 percent of the poverty gap, leaving 14.1 percent of families poor after the full effects of the safety net (excluding the value of medical benefits and insurance).

Rows 2 and 3 of table 8.1 show the same results for 1993 and 1984. The fraction of all families with income below the poverty line was about 30 percent in each year. The poverty gap per family was also about \$800 per month in each year. And in each year, between 66 percent and 73 percent of the poverty gap was filled by safety net programs.

Although the pretransfer poverty rates across years are similar, the percentage of total transfers received by pretransfer poor families and the percentage of total transfers used to fill the poverty gap have been falling over time. In 1984, 38 percent of transfers filled the poverty gap, while only 31 percent did in 2004. For families who remained poor after transfers, the monthly poverty gap (of \$580) in 2004 was larger than the monthly poverty gap (of \$480) in 1984. This raises the possibility that transfers in 2004 moved more near-poor families over the poverty line, per-

haps leaving those further away from the poverty line with even less assistance than before. We explore this possibility later in the chapter.

The Antipoverty Effectiveness of Specific Programs

Table 8.2 shows the antipoverty effectiveness of specific safety net programs in 2004 (in 2007 dollars). For this portion of the analysis, we also value Medicare and Medicaid. We assume that for most families, Medicaid was worth the cost of a typical HMO policy (for a discussion of ways in which Medicaid is more valuable than private insurance and ways in which it is less valuable, see Gruber 2003); for elderly or disabled families, we increase this by a factor of 2.5 to account for the greater medical needs of these groups. We value Medicare using 2.5 times the average cost of a fee-for-service plan, adjusting for regional cost differences.²⁹

Reading across the "all transfers" row (the sum of all social insurance and meanstested transfers shown in the table), the first entry shows \$95.9 billion of benefits, or \$1,238 per recipient family. Of these payments, 54.9 percent went to pretransfer poor families, and 22.8 percent reduced the poverty gap. These transfers filled 72.5 percent of the total poverty gap, which resulted in an after-tax and transfer

poverty rate of 12.0 percent (down from 30.3 percent) and a monthly poverty gap of \$8.3 billion.³⁰

The next rows show these effects for various programs and groups of programs. "All in-kind transfers" includes housing, food stamps, Medicare, Medicaid, and WIC. "All cash transfers" includes all other means-tested transfers. The "all social insurance" and "all means-tested transfers except the child credit and foster child payments" entries are self-explanatory. We focus on the effects of three sets of programs—all social insurance, all means-tested transfers (excluding child care credit and foster child payments), and the combined effects of all programs. If there were no means-tested transfers in place, 51 percent of social insurance would go to the pretransfer poor, these payments would close 48 percent of the poverty gap, and they would reduce the poverty rate from 30.3 percent to 18.8 percent. Similarly, if there were no social insurance programs in place, 74 percent of means-tested transfers would go to the pretransfer poor, these payments would close 36 percent of the poverty gap, and they would reduce the poverty rate from 30.3 percent to 23.5 percent. The *combined* effect of social insurance and meanstested transfers can be seen from the top (complete) line of table 8.2. The effect of all transfers was to close 73 percent of the poverty gap and reduce the poverty rate from 30.3 percent to 12.0 percent.

As expected, given their universality, the major social insurance programs— Social Security (OASI), disability insurance (DI), Medicare, unemployment insurance (UI), and workers' compensation—are not sharply targeted at pretransfer poor households. Disability insurance and unemployment insurance are the exceptions: 72 percent of DI benefits and 61 percent of UI benefits went to the pretransfer poor. Around half of the other social insurance program benefits went to individuals or families with incomes below the poverty line. About half of DI and UI benefits and 14 to 28 percent of the other benefits reduced the poverty gap. Given the large size of the programs, however, they filled a substantial part of the poverty gap. For example, about half of all Social Security benefits went to the pretransfer poor; if we include disability insurance (looking at OASDI), they reduced the poverty gap by 40 percent.

Means-tested programs typically provided a larger share of their benefits to the pretransfer poor than did social insurance programs. For example, 87 percent of food stamp benefits went to the pretransfer poor, and 84 percent of these benefits reduced the poverty gap. But because food stamps is a much smaller program than Social Security, it filled only about 6.3 percent of the poverty gap. Medicaid, SSI, housing assistance, and the EITC also closed the poverty gaps by 4.5 to 8.2 percentage points.

The Effects of the Safety Net Programs by Family Type

Table 8.3 compares differences in the effects of safety net programs on elderly families and eight non-elderly family types: (1) single-parent, (2) two-parent, (3) childless, (4) white, (5) black, (6) Hispanic, (7) employed, and (8) unemployed. The top row shows that \$48.6 billion in transfers per month, primarily Social Security and Medicare benefits, filled 95 percent of the poverty gap of the elderly, leaving them with a 7.8 percent post-transfer poverty rate. The second row shows that \$11.3 billion in transfers were received by non-elderly single-parent families—76 percent went to poor families and 37 percent reduced the poverty gap. Although these transfers filled 82 percent of the poverty gap, 13.8 percent of non-elderly single-parent families remained poor. The \$15 billion in monthly transfers for non-elderly two-parent families reduced their poverty gap by 76 percent, resulting in a poverty rate of 5.1 percent.

Non-elderly black and Hispanic families and individuals had higher pretransfer poverty rates than non-elderly white families, received (on a per capita basis) more transfer payments, and, for those who were poor, had a similar depth of poverty (as measured by the poverty gap). Despite receiving more in average transfers, black and Hispanic families and individuals had post-transfer poverty rates that were around three percentage points higher than those of white families and individuals.

Table 8.3 calls attention to several holes in the safety net. First, the tax and transfer system filled only 50.7 percent of the poverty gap for non-elderly childless families in 2004, compared to 75.5 percent for two-parent families with children, and 82.1 percent for single-parent families with children. Other than food stamps, these families had few public assistance programs they could access in the absence of a disability, though, as discussed earlier, strengthening their safety net runs the risk of creating incentives to not work or not invest in skills that could lead to greater self-sufficiency. Second, post-transfer poverty rates remained high for single-parent families with children (13.8 percent) as well as for black and Hispanic families (15.0 percent and 15.4 percent, respectively). Third, non-elderly families with no employed individuals had an exceptionally high post-transfer poverty rate, 44.1 percent. As we discuss in the next section, changes in the nature of the safety net over the past twenty years have increased the economic vulnerability of family heads who are unable or unwilling to work.

The Changing Nature of U.S. Antipoverty Programs

The safety net has changed in striking ways for the non-elderly. The changes are evident, in part, in figure 8.3, which shows the reduction from 1970 to 2007 in AFDC-TANF expenditures, which historically went to nonworkers, and the increase in EITC benefits, which go overwhelmingly to low-income workers with children. Other than food stamps and housing benefits, non-elderly families or individuals with very low or no earnings and patchy employment histories had no safety net to draw on.

We illustrate changes in the safety net for different groups of families with a series of figures that illustrate the average monthly benefits available to low- and moderate-income families. Figure 8.6 shows the trend in average benefits (over all programs but excluding Medicare and Medicaid) received by non-elderly,

FIGURE 8.6 / Average Monthly Benefits for Single-Parent Families, 1984, 1993, 2004

Source: Authors' calculations based on wave 1 of the 1984, 1993, and 2004 SIPP (U.S. Bureau of the Census, various years).

nondisabled, single-parent families. On the horizontal axis, we classify families by their pretransfer income, restricting the sample to families with incomes between zero and 200 percent of the poverty line.³¹ On the vertical axis, we plot average transfer program benefits, excluding Medicare and Medicaid but including all other transfers enumerated in table 8.2. The three lines show average benefits (in 2007 dollars) for families in the 1984, 1993, and 2004 SIPP surveys.³² Focusing first on the two lines for 1984 and 1993, we note that the largest benefits were received by those with no income and that average benefits fell as income as a percentage of the poverty line rose. This accords with the traditional structure of a transfer program, where benefits are phased out as income rises. In fact, the negative slope of the lines in figure 8.6 reflects the fact that benefits are phased out as income increases, as we discussed earlier. The steepness of the line in 1984 and 1993 vividly highlights the weak incentives that single parents faced to earn income in the paid labor market. In 1993, for example, families with no market income received around \$1,200 of benefits, but as income increased to roughly 25 percent of the poverty line, average benefits fell to around \$800.

The situation in 2004 was quite different, for the slope of the benefit line below 25 percent of the poverty line was actually positive, implying a subsidy to work (or a negative tax rate) on average. We noted that development earlier and traced it to the EITC and reductions in TANF tax rates. At the same time, however, average benefits received by a single parent with no income were 45 percent lower than in 1993. This was, in some sense, the "price" of increasing work incentives (namely, making things relatively worse off for those at the bottom). We also note that the

FIGURE 8.7 / Average Monthly Benefits for Two-Parent Families, 1984, 1993, and 2004

Source: Authors' calculations based on wave 1 of the 1984, 1993, and 2004 SIPP (U.S. Bureau of the Census, various years).

increases in benefits for higher-income families, that is, the work incentives provided, extended all the way up through the highest income level shown in the figure (200 percent of the poverty line). The income increases were driven almost solely by the Earned Income Tax Credit and, as income got higher, the refundable child credit.³³

Figure 8.7 shows a similar pattern for married couples with children.³⁴ Average benefits for nondisabled, non-elderly married couples with children in 2004, with no income, were about 48 percent of the average benefits available in 1993. Once income exceeded roughly 40 percent of the poverty line, average benefits in 2004 were larger than comparable families received in earlier years.

Figure 8.8 shows average benefits for nondisabled, non-elderly childless families and individuals. Again, average benefits for those with very low or zero income were lower in 2004 than they were in earlier years. The EITC available to childless taxpayers, which was initiated in 1994, is evident in the figure. Otherwise, few benefits were available, and this fact had not changed for twenty years.

There are substantial numbers of families or individuals reflected in figures 8.6 through 8.8 with incomes below 25 percent of the poverty line.³⁵ The education of the "deep poor" rose over time, the number of children fell over time, and the fraction of employed families (defined as at least one person in the family being employed in all four months of the reference period) went from 15 percent in 1984 to 10 percent in 1993, to 36 percent in 2004. Thus, it appears that the incidence of regular, but sporadic and poorly compensated, work was much greater in the

FIGURE 8.8 / Average Monthly Benefits for Childless Families, 1984, 1993, and 2004

Source: Authors' calculations based on wave 1 of the 1984, 1993, and 2004 SIPP (U.S. Bureau of the Census, various years).

2004 SIPP. This conclusion is tempered, however, by three considerations. First, the SIPP employment question changed in 2004. Second, surely families and individuals with incomes below 25 percent of the poverty line supplemented public transfers with "off-the-books" resources, but the SIPP provides no insight into this phenomenon. Third, market income may also have been underreported by low-income individuals, and the magnitude of this underreporting may have changed over time in the SIPP.

The sample for figure 8.9 is restricted to elderly families (or unrelated individuals). Unlike the striking changes for the poorest non-elderly families, the average benefits received by poor elderly families in 2004 were similar or slightly higher than those received in 1993 (and larger than those received in 1984). This is largely due to the fact that Social Security was stable over this period. In contrast, the changes for non-elderly households were consistent with the changing incentives embodied in the safety net: as greater emphasis was placed on work, fewer benefits were available to those who, for one reason or another, were unwilling or unable to work.

THE FUTURE OF ANTIPOVERTY POLICY

Between 1975, the first year the EITC existed, and 2005, total spending on all means-tested cash and in-kind transfers (excluding Medicaid) averaged 2.0 percent of GDP, ranging between 1.8 percent and 2.5 percent. In 2005 it was 1.8 percent of

FIGURE 8.9 / Average Monthly Benefits for Elderly Families, 1984, 1993, and 2004

Source: Authors' calculations based on wave 1 of the 1984, 1993, and 2004 SIPP (U.S. Bureau of the Census, various years).

GDP, near its thirty-one-year low. Transfers now do less to close the poverty gap than they did before. As shown in table 8.1, transfers reduced the poverty gap by 66.2 percent in 2004, while the comparable figures were 72.7 percent in 1993 and 70.9 percent in 1984. The difference between pre- and post-transfer poverty rates was 16.2 percentage points in 2004, 16.9 percentage points in 1993, and 15.4 percentage points in 1984. But the depth of poverty for those remaining poor appears to have increased substantially—the after-transfer poverty gap in 2004 (all in 2007 dollars) was \$580, compared to \$496 in 1993 and \$479 in 1984. These patterns are driven by substantial changes in the antipoverty policy mix, which has resulted in large changes in the resources available to families and individuals in different circumstances.

The contrast in levels and, to a lesser extent, trends in social expenditures between the United States and other industrialized countries is striking. Smeeding (2008) calculates a consistent set of social expenditures (including cash, near-cash, and housing expenditures) as a percentage of GDP for five groups of countries— Scandinavia, northern Continental Europe, central and southern Europe, "Anglo" (Australia, Canada, and the United Kingdom), and the United States—between 1980 and 1999. Spending ranges between 2.7 percent to 3.6 percent of GDP in the United States, a far lower level than in every other country group. The other Anglo countries averaged between 4.8 percent and 7.8 percent of GDP, similar to the central and southern European countries. Northern Europe and the Scandinavian countries averaged between 8.1 percent and 15.3 percent of GDP.

The trends across country groups vary, though most country groups increased expenditures as a share of GDP between 1980 and 1999. The United States did not.

Why has U.S. antipoverty spending been low and relatively stable given the nation's persistent and high poverty rates, at least by international standards? A number of factors are relevant. There may be indifference or antipathy to the poor on the part of the public (Bane, this volume). Voters and policymakers may be skeptical that we know what works and may believe that some well-intentioned policies have counterproductive consequences. Lastly, the fiscal policy climate over much of the previous thirty years, with a respite in the 1990s, has been difficult.

Developments in 2008 promise both continuation and possible change in these trends. The recession that began in 2008 may be long and deep, leading to both increases in pretransfer poverty and declines in government revenue, causing further fiscal distress at the federal and state levels. On the other hand, the voters in the 2008 election, with their election of President Obama and his progressive agenda, signaled a desire for social policy change that, among other features, is likely to promote a more equitable distribution of income and public benefits. How the twin pressures of increased economic contraction and fiscal stringency, on the one hand, and greater desire for activist government intervention, on the other, play out remains to be seen.

Given the severity of the economic downturn that began in 2008 and the magnitude of the likely fiscal policy response, it is an unusually difficult time to speculate on the evolution of antipoverty and social insurance programs. The policy agenda of many will be to broaden health insurance coverage, improve education access, expand tax credits for some groups of low-skilled workers, and extend (and possibly enhance) unemployment insurance benefits. But there nevertheless appears to be little appetite for tax increases among the population or political leadership, so the potential for widespread, durable change in social policy is not clear at this point.

To the extent that durable change occurs, we hope policymakers will be influenced by the large and growing body of evidence that work-based antipoverty strategies like the Earned Income Tax Credit, the Canadian Self-Sufficiency Project, the Wisconsin TANF program (W-2), and the Minnesota Family Investment Program can both increase work and the after-tax incomes of poor families. These policies require that the poor work to receive benefits but are structured so that greater work effort increases disposable income. Although such a work-based safety net aligns assistance with the fundamental values of Americans, we have not effectively struck a balance between supporting work and sensibly treating those families (and the children therein) who, for one reason or another, are unable or unwilling to work (Blank and Kovak 2009).

Also, while the 1996 welfare reform increased work, the earnings of most individuals who left welfare were still well below the poverty line, even many years after their exit. Hence, the degree to which work can be the primary antidote to poverty depends on the ability of low-skilled people to maintain employment that, over time, leads to higher incomes that allow families to be self-sufficient. More work is needed to develop effective ways of increasing the earnings of disadvantaged workers (Holzer, this volume; Heinrich and Scholz 2009). Major changes in poverty will not be achieved by simply reshuffling the 1.8 percent of GDP that is spent on cash and in-kind means-tested transfers (excluding Medicaid). If antipoverty spending as a fraction of GDP simply increased to its *average* level over the last thirty-one years of 2.0 percent, there would be an additional \$26.5 billion for new initiatives. These funds could be used to (1) expand successful state-level welfare reforms and provide new funding sources for child care and health insurance benefits that increase the attractiveness of work; and (2) augment the safety net, pursue effective human capital development, expand rental housing subsidies, and ensure that states have sufficient resources to handle families affected by TANF time limits in the way they see fit.

In the absence of a renewed antipoverty effort, many households will continue to be unable to afford adequate food, housing, and shelter. Our high poverty rate contributes to an erosion of social cohesion, a waste of the human capital of a portion of our citizenry, and the moral discomfort of condoning poverty amid affluence.

a. Average monthly number of recipients.
 b. Average monthly number of recipients, based on nine-month average.

We are grateful to Mark Duggan, Jon Gruber, Bob Plotnick, Chad X. Ruppel, the conference organizers Maria Cancian and Sheldon Danziger, and conference participants for providing helpful advice.

NOTES

- 1. In 2008 the OASDI program was financed by a 6.2-percentage-point payroll tax levied on employers and employees (for a combined 12.4 percent tax) on earnings up to \$102,000. These tax receipts are credited to the Social Security trust fund. To receive benefits, a worker must have at least forty quarters of employment in jobs covered by the Social Security system. (Most jobs are now covered.) Workers (who are not disabled) can begin drawing reduced benefits as early as age sixty-two; the normal retirement age is sixty-seven for workers born after 1959. Benefit payments increase (nonlinearly) as retirement is delayed until age seventy-two, at which point benefits no longer increase with age of retirement.
- 2. The census money income concept to measure poverty is pretax and includes earnings, unemployment compensation, workers' compensation, Social Security, Supplemental Security Income (SSI), public assistance, veterans' payments, survivor benefits, pension or retirement income, interest, dividends, rents, royalties, income from estates, trusts, educational assistance, alimony, child support, assistance from outside the household, and other miscellaneous sources. See Meyer and Wallace (this volume) for more details.
- 3. All dollar amounts are given in 2007 dollars unless otherwise noted. Descriptions of statutory program rules refer to the year in question (in this example, 2008).
- 4. Medicare is financed by a 1.45 percent payroll tax on uncapped earnings levied on employers and employees (for a total tax of 2.9 percent).
- 5. Timothy Smeeding (1982) discusses these issues. Gary Burtless and Sarah Siegel (2004) discuss the issues that arise in accounting for health care spending and insurance when measuring poverty.
- 6. From 1959 to 1974, real Social Security spending increased 210 percent, a much sharper growth rate than in other fifteen-year periods. For example, real Social Security spending increased 110 percent between 1970 and 1985, and 29 percent between 1991 and 2006.
- 7. Authors' calculations from data provided by the Center for Medicare and Medicaid Services and the Social Security Administration.
- 8. The federal portion of unemployment insurance is financed by a 0.8 percent tax levied on employers on the first \$7,000 of wages paid to each covered employee. The states levy additional, modest taxes to finance their programs.
- 9. Although UI eligibility varies by state, typically one must have worked for at least two quarters of the previous year in covered employment, be actively seeking work, and have lost one's job through no fault of one's own. A worker can generally receive a maximum of twenty-six weeks of benefits, and these benefits generally replace between 50 and 70 percent of the individual's average weekly pretax wage up to some state-determined maximum.

- 10. "Substantial gainful activity" is defined as work that involves significant physical or mental effort and is done for pay or profit. Complex regulations promulgated by the Commissioner of the Social Security Administration define disabilities and substantial gainful activity, though average monthly earnings above some threshold (\$940 in 2008) demonstrate substantial gainful activity for people with an impairment other than blindness.
- 11. David Autor and Mark Duggan (2003) examine the factors affecting DI caseloads over time.
- 12. Throughout this chapter, figures on Medicaid recipients and expenditures include those for SCHIP.
- 13. In 2008 the SSI income test restricted countable income to less than the federal benefit rate of \$637 a month. Countable income excluded \$20 a month, the first \$65 a month from earnings, 50 percent of earnings exceeding \$65 per month, and food stamps. This implies that a person could have earned income of up to \$1,359 per month and still be eligible for SSI. A couple with only wage income could have had earnings of \$1,997. An individual also cannot have assets exceeding \$2,000 (\$3,000 for couples), though houses and generally automobiles are not counted. An applicant is expected to first file for all other available benefits, including DI if they are eligible.
- 14. The EITC is a refundable credit that taxpayers can receive after filing their tax returns. It seeks to encourage individuals with low earnings to increase their work hours. In 2008 low-income working families with two or more children could get a credit of 40 percent of income up to \$12,060, for a maximum credit of \$4,824, which stays at this level as earnings increase from \$12,060 to \$15,740. Their credit is reduced by 21.06 percent of earnings between \$15,740 and \$38,646. Those with one child can get a credit of 34 percent on income up to \$8,580, for a maximum credit of \$2,917. Childless taxpayers can get a credit of 7.65 percent on income up to \$5,720, for a maximum credit of \$438. See Hotz and Scholz (2003) for further discussion.
- 15. Programs designed to enhance human capital are discussed in Jacob and Ludwig (this volume) and Holzer (this volume).
- 16. Families receiving SSI or TANF also receive food stamps. Others must have incomes below the poverty line after subtracting a \$134 per month standard deduction, 20 percent of earnings, dependent care and large shelter expenses, and child support payments. Total income cannot exceed 133 percent of the poverty line. A family must have less than \$2,000 in assets (\$3,000 if a member is elderly). Vehicles (under \$4,650 in value) and houses do not count for the asset tests. PRWORA disqualified most permanent resident aliens and mandated work activities for able-bodied adults without dependents, who are now generally eligible for only three months of benefits in a thirty-six-month period if they are not working.
- 17. The Dependent Care Tax Credit, enacted in 1954, is a nonrefundable tax credit. However, it provides no benefit to families with incomes at or below the poverty line because these families do not have positive federal income tax obligations.
- 18. Medicaid is considerably larger than the combined value of the other in-kind transfers in recent years. In-kind transfers including Medicaid grew at an annual rate of 11.2 percent in the 1970s, 4.5 percent in the 1980s, 6.0 percent in the 1990s, and 6.2 percent between 2000 and 2005.

- 19. The poverty lines are the official Census Bureau thresholds for each year. For the 2004 thresholds, see U.S. Census Bureau, "Poverty," available at: http://www.census.gov/ hhes/www/poverty/threshld/thresh04.html (last updated August 29, 2006).
- 20. Martin Feldstein and Jeffrey Liebman (2002) survey the behavioral effects of Social Security. Medicare is discussed in Swartz (this volume).
- 21. In addition to the chapters in this volume and work cited elsewhere in this chapter, see, for example, reviews by Sheldon Danziger, Robert Haveman, and Robert Plotnick (1981) and by Robert Moffitt (1992). Recent surveys on specific programs include Currie (2003) on food and nutrition programs, Olsen (2003) on housing assistance, and Daly and Burkhauser (2003) on SSI.
- 22. Families with somewhat higher earnings can still face high tax rates if they begin to pay federal and state income taxes and payroll taxes, have the EITC phased out, and perhaps have other benefits phased out.
- 23. It is also not clear that increasing saving for precautionary motives—that is, saving "for a rainy day"—should be encouraged, since such saving takes away from current consumption.
- 24. James Ziliak (2005) provides a wide-ranging discussion of the issues that arise in measuring poverty and calculates the evolution of the aggregate poverty gap over time. Using data from the Current Population Survey (CPS) (Ziliak 2008), he calculates the effects of various safety net programs on the poverty gap in 1979, 1982, 1989, 1991, 1999, and 2001, broken out by a wide range of household demographic characteristics. While Ziliak's conclusions differ from ours in some respects—he finds modest declines in poverty gaps over time where we find increases—he, like us, finds that a declining fraction of the poverty gap is being filled by transfers and that there have been marked changes in the distribution of inequality within subgroups (for example, single mothers).
- 25. The child credit was enacted in 1997, so it is only reflected in 2004.
- 26. The same is true for Medicare, which is reflected in tables 8.2 and 8.3.
- 27. The state FMRs are population-weighted averages by county (or major metropolitan area). We adjust by the number of bedrooms needed for families of different sizes, assuming that childless individuals or couples live in a one-bedroom dwelling and families with one or two children live in a two-bedroom dwelling. An extra bedroom is added for each child over two.
- 28. If a family has a poverty gap of \$100 and the program provides \$1,000 of benefits, only \$100 would be included in the "percentage of total used to alleviate poverty" column.
- 29. The data come from the Kaiser Family Foundation and Health Research and Educational Trust, "Employee Health Benefits: 2005 Summary of Findings," averaging figures from the 2003 and 2005 Annual Employer Health Benefits Surveys, available at: http://www.kff.org/insurance/7315/sections/upload/7316.pdf; Kaiser Family Foundation, "Employer Health Benefits: 2003 Annual Survey: Cost of Health Insurance," available at: http://www.kff.org/insurance/upload/Kaiser-Family-Foundation-2003-Employer-Health-Benefits: 2005 Annual Survey: Cost of Health Insurance," available at: http://www.kff.org/insurance/upload/Kaiser-Family-Foundation, "Employer Health Benefits: 2005 Annual Survey: Cost of Health Insurance," available at: http://www.kff.org/insurance/7315/sections/upload/7315Section1.pdf (accessed April 27, 2008). For 1984 and 1993, we used similar information from Kaiser Family Foundation and Health Research and Educational Trust, "Employee Health Benefits: 1999 Annual Survey," available at: http://www.kff.org/insurance/upload/The-1999-Employer-Health-Benefits-Annual-Survey.pdf (all accessed September 2, 2008).

- 30. The difference between the "all transfers" row in table 8.2 and the 2004 data in table 8.1 simply reflects the valuation of Medicare and Medicaid (in table 8.2), which reduce poverty by 2.1 additional percentage points—from 14.1 to 12.0 percent.
- 31. Among all families with incomes below twice the poverty line in 2004, about 29 percent had almost no reported income (zero to 25 percent of poverty), and 39 percent had incomes below 50 percent of poverty. The remaining 61 percent were fairly evenly distributed between 50 and 200 percent of the poverty line.
- 32. The data are smoothed with a Stata-supplied local polynomial function that uses an Epanechnikov kernel.
- 33. Given the sharp increases in health care costs over time, the magnitude of the cross-year differences in figures 8.6 through 8.9 are smaller, but the qualitative patterns are similar if Medicare and Medicaid are included. For this discussion, we prefer the figures without health care spending because they aptly characterize the transfers that households receive to provide food, shelter, clothing, and other nonmedical necessities.
- 34. For clarity, the Y-axis scales differ in figures 8.6 through 8.9.
- 35. For two-parent families in 1984 and 1993, 11 percent of those with incomes below 200 percent of poverty had incomes below 25 percent of the poverty line. For childless individuals in 2004, 32 percent of those with incomes below 200 percent of the poverty line had incomes below 25 percent of the poverty line.
